Chemical & Metallurgical Engineering

A Semi-monthly Technical Newspaper,
Being the Incorporation of
Electrochemical and Metallurgical Industry
and Iron and Steel Magazine

Volume XX

From January 1 to June 15, 1919

436845
3. 7. 45

NEW YORK:
McGRAW-HILL COMPANY, Inc.

INDEX TO VOLUME XX

GENERAL ALPHABETICAL INDEX

*Entries from the Synopsis of Periodical Literature are indicated by S; from the Analysis of Current Electrochemical, Chemical and Metallurgical Patents by P; Papers read at society meetings but not printed in full are indicated by N. Illustrated articles are indicated by **

A

Acetic acid, From wood pulp waste..... 542
——Manufacture, Dreyfus. (P.)..... 248
Acetone, From wood, Bassett..... 190
——From wood pulp waste..... 542
Acid eggs, Cast iron, Bursting of. (S.)... 433

ACID:

——Mixed, Action on cast iron. (S.).... 433
——Mixed, Plant at Nitro..... *406
——Surplus, War Department..... 319
Air conditioning 405
Alaska, Ammoma leaching at Kennecott.. 328
Albumen glues 601
Alcohol, Methyl, From wood pulp waste.. 542
Alien Property Custodian, Report on chemical industries 264
——Report on metal industry 313

ALLOYS:

——Acid-proof, Rossi. (P.)..... 597
——Aluminium-Tin, Equilibrium diagram. 423
——Chemically reactive. (S.) 594
——Chromon. 437
——Colloid-chemical nature. Alexander. (N.) 212
——Copper-aluminium, Equilibrium diagram 424
——Copper, Determination of phosphorus in 58
——Magnesium-lead. (S.) 594
——Norwegian bronze 179
——Silicon, Hydrogen from *289
——Steel, Flakes in *216
——For helmets and armor, Coyle.... 618
——Zinc-copper-aluminium, Guillet and Bernard. (S) 645
——Zinc-iron 530
Almaden, Spain, Mercury production at, Sterner-Rainer *32

ALUMINA:

——Beta, Saunders. (P.)..... 87
——Crystalline, Tone. (P.)..... 87
——From impure bauxite, Saunders. (P.) 87
——Production, Larson. (P.)..... 487
——Purification, Hornsey. (P.)..... 487
——Purification, Saunders. (P.)..... 87

ALUMINIUM:

——Bronze, Die casting of, Rix. (S.).. 135
——Bronze industry, Morse..... 212
——Bronze, Properties of 163
——Diseases of *280
Alunite, Potassium sulphate from, Chappell. (P.) 249
Ambrine treatment for burns 288
American Bureau of Welding, Election of officers 456
American Ceramic Society, Pittsburgh meeting 180
AMERICAN CHEMICAL SOCIETY:
——Buffalo meeting, Report..... *390

AMERICAN ELECTROCHEMICAL SOCIETY:

——New York meeting, Program..... 273
——Report *379
——Fall meeting, Announcement 616
——Pittsburgh Section 31
American Electroplaters' Society, Research fund 501

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS:

——Boston meeting, Announcement..... 334
——Program 504
——Chicago meeting, Program..... 37
——Report of..... *115
AMERICAN INSTITUTE OF MINING ENGINEERS:
——Chicago meeting, Announcement..... 505
——New York meeting, Program 101
——Report *208
——Pyrometry symposium, Program.... 455
American Paper and Pulp Association:
——New York meeting *184
Americaa Metal Co., German-owned shares sold 430
American-Scandinavian Foundation 505
American Smelting and Refining Co., Report 615
American Welding Society 265
——1st meeting, New York..... 400

AMMONIA:

——From cyanides and ferrocyanides. (P.) 431
——From cyanamide. Muscle Shoals.... 14
——Leaching of copper ores. Eddy..... 328
——Nitric acid from. Landis. (P.)..... 431
——Oxidation of. Landis..... 470
——Oxidation of. Parsons. (N.)..... 502
Ammonium nitrate, Controlling crystallization. Bolling 401
——Perryville plant *320
——Phases of 321
——Production at Muscle Shoals..... *17
Ammonium perchlorate, Aanensen. (P.) 597
Ammonium sulphate, Production. Larson. (P.) 487

ANALYSIS:

——Aluminium in plain steel 588
——Chromium in steel 589
——Copper, Electrolytic, without rotating cathode 452
——Ferromanganese 53
——Jones reductor for steel 523
——Nickel in steel, Modified cyanide method. Miller. 613
——Phosphorus in copper alloys..... 58
——Potash in cement by perchloric acid method 452
——Red lead, Edwards 35, 260
——Sulphite liquor. Baker. (N.)..... 185
——Sulphur dioxide in gases. (S)..... 541
——Uranium in chrome tungsten steel... 524
——Uranium in plain steel..... 523
——Vanadium in steel 589
——Zirconium in steel 588
Aniline hydrochloride. Ahlum. (P) ... 648
Anti-dumping law advocated..... 116
Anti-freezing mixtures containing calcium chloride. Rudnick. (N.)..... 394
Apparatus, Chemical, Buflokast *395
Arc welder, Portable 436
Argentina, Linseed production 220
Armor, Alloy Steels for. Coyle 618
Arndt gas balance *291
Asbestos, Platinized. Frabetti. (P.)..... 487
Ash, Coal, Fusibility of. Selvig et al.... 274
Ashpit door, Air tight..... 598
Asphaltic sandstone, Extraction of kerogens from 31
Australia, Dye importation prohibited.... 420
Auto-recorder, CO_2 ..... *243

B

Ball mills, Fine crushing in, Davis. (N.) 210
Barium industry, Future of. Rollin..... 163
Barium products, Uses of..... 164
Bartlesville Zinc Co., Sintering zinc residues, Stock *525
Bauxite, Purification of. Saunders. (P.) 87
Bearings, Detecting overheating of..... 577
Beer Sondheimer & Co., Organization.... 316
Beet-sugar, Production in Utah and Idaho 560
Belting for power trasmission. Wilson. (N.) 117
Belting, Leather, Specifications. (S.).... 543
Benzol, French production 57

BIBLIOGRAPHIES:

——Chemical literature:
—— Biochemistry 580
—— Mining and metallurgy 580
—— Organic 578
——Cottrell, F. G., Articles and patents... 114
——Metallic coatings for rust-proofing iron and steel 591
——Milling calculations. Lewis..... 233
Bi-meter CO_2 recorder *243
Bituminous roofing materials. Wilson. 425, 484
Black Hills Mining Men's Association.... 207
Black sand deposits in..... 79
Black sands, Platinum in..... 101
Blistering in sheet steel enamel. (N.).... 182
Blood albumen glues 601
Boiler plants, Fuel economy in. Kershaw. 176, *241, *291

BOOK REVIEWS:

——Allen. Mill and Cyanide Handbook... 361
——Auld. Gas and Flame in Modern Warfare..... 439
——Ellis. Hydrogenation of Oils..... 601
——Ferry. Handbook of Physical Measurements 438
——Gill. Handbook of Oil Analysis..... 90
——Hale. Applications of Electrolysis in Chemical Industry 438
——Johnson. Principles, Operation and Products of the Blast Furnace.... 438
——Laucks. Commercial Oils..... 602
——Lunge. Technical Chemists' Handbook 90
——Manlove and Vickers. Scrap Metals. 194
——Megraw. Flotation Process 440
——Morgan. Organic Compounds of Arsenic and Antimony 90
——Shuey. Bibliography of Foreign Trade Publications 136
——Smith. Electro-Analysis 601
——Smith. The Zinc Industry..... 136

BOOK REVIEWS—*Continued:*

——Steinmetz. General Lectures in Electrical Engineering 439
——Villavecchia. Treatise on Applied Analytical Chemistry 439
——Wile. Explaiming the Britishers..... 438
Boxes, Metal strapping on..... 483
Brass, Cartridge, Comparison of grain-size and Brinell hardness. (N.)..... 212
——Corrosion in sea water. Bruhl..... 239
——Influence of certain variables on anneal of cold-worked alpha brass. Phillips and Gerner..... *622
——Pyrometer for 436
Brick, Manufacture at Kingsport..... 568
Briquetting brittle metals. Vogel. (P).. 647
British Columbia, Electric pig iron for... 206
——Electric smelting, Commercial feasibilty 630
——Mineral production, 1918..... 148
British import restrictions.....189, 288, 600

BRONZE:

——Alloy, Norwegian 179
——Aluminium, Die casting. Rix. (S.). 135
——Aluminium, Properties of..... 163
——Manganese, Manufacture. (N.).... 212
——Phosphor, Properties of..... 163
——Pyrometer for 430
Brooklyn, Polytechnic Institute dinner.... 505
Bucher process, Davis. (N.)..... 394
Buffalo, American Chemical Society meeting *390
Buffalo Foundry & Machine Co..... *395
——Vacuum drum drier..... *642
Buflokast apparatus, Making..... *395
Bureau of Mines, Mesothorium research.. 168
——New laboratories in Pittsburgh..... 617
Bureau of Standards, Electroplating work. 501
——Standard samples, Distribution of.... 276
Burns, Treatment of..... 288
By-products, Principles of. Steinmetz. (N.) 184

C

Cable, Hoisting, Failure of. Robertson. (N.) 263
Calcium carbide, Preparing charge for. Becket. (P.) 431
Calculations, Milling. Lewis..... 224
California, Chromite deposits in..... 79
——Manganese and chromium in..... 319
——Mineral production, 1918..... 149
Calignate, Acetone and methyl alcohol from. (S.) 542
Calumet & Arizona Mining Co., Report.. 615
Cambridge bi-meter CO_2 recorder..... *243
Canadian graphite industry 81
Canadian Mining Institute:
——21st Meetiog, Announcement 136
—— Report 262
Carbazol, Purification of. Weiss. (P.).. 596
Carbon Dioxide, Novel use..... 185
Carbon dioxide recorders, see Recorders, carbon dioxide.
Case-hardening, Shirmer. Richards. (N.). 213
Casting tools, Davidson process. Johnson. (N.) 213
Castings, Chemical, Pouring..... *396
Castings, Die, Pack. (N.)..... 212
Caustic Pots, Furnace settings, Nickle... *65
——Correction 261
Caustic Soda, French production..... 58
Celluloid-glass lenses, Rosenthal. (N.).. 504
Celluloid, Substitute, Zeisberg. (P.).... 296
Cement, Blast furnace slag-lime-gypsum.. 25
—— Resistance to sulphate corrosion... 28
—— Tests of..... 25
——Manufacture at Kingsport 568
Census of chemical imports 562
——Comment by Bernhard C. Hesse..... 559
Centrifugal agitator. Jacoby..... 598

CHARTS:

——Showing use of exhaust steam..... 18
——Alignment:
—— Indentation of steel balls under pressure 192
—— Power data for electrolytic zinc. Supplement to Feb. 15.
Chemical Alliance, Export statistics..... 295
——New York meeting 100
Chemical elements, Melting points of..... 351
Chemical Engineer, Modern training of. McKee. (N.)..... 503
Chemical Exposition plans 561
Chemical Foundation, Organization of.... 265

CHEMICAL INDUSTRY:

——At Kingsport, Tenn.....*565, *639
——Engineering research in. Field..... 84
——Foreign competition in..... 118

CHEMICAL INDUSTRY, *Continued*:
——Foreign trade, Aids to 189
——German methods, Choate, (N.) 392
——In France during war, Maoussa 56
—— (S.) 542
——Intelligent location of 311
——Made permanent, Thompson 118
——Organic, Future of, Hibbert 335
——Organization of 123
——Present conditions in, Toch, (N.) .. 116
——New Jersey, Recent developments, (N.) 39
——Reconstruction aspects, Gudeman, (N.) 116
——Report of Alien Property Custodian. 264
——Tariff Commission and, Culbertson, (N.) 392
Chemical literature, Art of searching, Hibbert 578
Chemical market
44, 92, 139, 196, 251, 299, 363, 443, 490, 546, 603, 650.
Chemical specifications, Cohoe 539
Chemical warfare, Effectiveness, Hendrick 152
Chemical Warfare Service, Pershing confirmands 601
Chemical war secrets, Gudeman, (N.) .. 117
Chemists' Club Scholarships 620
Chicago, Amer. Inst. of Chem. Eng. meeting *115
Chile, Instituto Cientifico Industrial 205
Chloridizing complex ores 207
Chlorine, French production 57, 542
Chlorine in sanitation 414
Chromite, Concentration of 80
Chromium, Canadian practice, (N.) 263
Chromon, Pyrometer protection tubes 437
Civil Service examinations: 318, 399, 589, 618
Claude helium plant at Fort Worth *110
Clays, American, Maynard, (N.) 185

COAL:
——Ash, Fusibility of, Selvig et al. 274
—— Pennsylvania, Selvig and Fieldner 629
—— Improved furnace for fusion point, Lovejoy 538
——Clinchfield, Analysis of 567
——Distillation at low temperatures 78
——Lubricating oils from 79
——Powdered, For blast furnaces, Wotherspoon, (N.) 263
——Powdered, Nodulizing flotation concentrates with, Draper 621
Coal tar products, Tariff amendments 179
Colloidal silver chloride 260
Colloid-chemical viewpoint of metals, Alexander, (N.) 212
Colloids in Flotation, Reply to criticism ... 52
Colorado Fuel & Iron Co., Americanization work *529
Combustion, Surface, Roasting by, McCourt, (P.) 297
Compensation laws, Need of revision 416
Concentrates, Flotation, Roasting, Fullam, (P.) 86
Concentrating system, Gahl, (P.) 432

CONCRETE:
——As chemical engineering material, Toch 222
——Defects of 222
——Methods for protection of 223
——Tanks, Reinforced, Frerichs 234
——Waterproofing 222
——Work at large acid plant 408
Condenser tubes, Corrosion of, (S.) 594
Coniagas Mines, Ltd., Report 149
Consolidated Arizona Smelting Co., Report 616
Construction and Operation
47, 95, 142, 199, 255, 303, 366, 446, 495, 550, 607, 654.
COPPER:
——Alloys, Determination of phosphorus in 58
——Analysis, Electrolytic, without rotating cathode 452
——Coating steel with, Silverman, (N.) 211
——Companies, Employees to meet Secretary of Labor about 136
——Cupro-phosphorus, Jeffs, (P.) 249
——Electrolytic refining, Laboratory plant, Hayward *240
——Flotation concentrates, Nodulizing, Draper 621
——Flotation plant at Ohio Copper Mill. 6
——Iron for precipitating, Johnson, (P.) 596
——Leaching oxidized ores 559
——Ores, Ammonia leaching of, Eddy .. 328
——Plating, Automatic, Richards, (N.) 211
——Production and price 455
——Recovery from sulphate solution, (P.) 432
——Russian smelter equipment, Carlyle, (N.) 263
——Volatilization of cuprous chloride on melting, (N.) 211
Cores for chemical castings *396
Corrosion, (See also Metal protection)
——Brass in sea water, Bruhl 239
——Condenser tubes, (S.) 594
——Nature of 458
——Bibliography 591
Cottrell, F. G., Bibliography of articles and patents 114
Cottrell precipitator, At Kingsport 569
——Effect of dielectric deposits, (S.) ... 89
——History of, Chandler 103
——In alkali pulp industry, (N.) 184
——In metallurgical plants, Thum *59
——Portable, Lamb, (N.) 386
Crane, Locomotive, Specifications, (S.) .. 433
Cripples, Use of in industry, Munroe, (N.) 210
Crystal crushing, Example of 72, 309
Crystals, Growth of, (S.) 595
Crystallization control, Bolling 401
Cuprodesclozite, Vanadium, lead and copper from, Conley 465
Cupro-phosphorus, Jeffs, (P.) 249
Cuprous chloride, Volatility, (N.) 211
Current Market Reports
42, 91, 137, 194, 250, 298, 362, 441, 489, 545, 602, 649.
Cyanamide, French production 57
Cyanamide Process at Muscle Shoals 9, 13
Cyanide plants, Calculating extraction ... 225
Cyanides, Alkali, Ammonia from, (P.) ... 431
—— Separation from hydroxide, Metzger, (P.) 431

D

Davidson tool-casting process, Johnson, (N.) 213
Decomposition of metals, Krynitzky. *277 *421
—— Correction 501
Deformation, Effect on mechanical properties of metals, Jeffries, (N.) 211
Denitrating plant at Nitro, Hollister *406
Depolarizers, Manganese dioxide, (P.) 432
Die casting of aluminium bronze, Rix, (S.) 135
Die castings, Pack, (N.) 212
Dielectric deposits, Effect on Cottrell process, (S.) 89
Disabled men, Opportunities for 319
Distillation of coal at low temperatures ... 78
Drier, Vacuum drum *642
Dye plant, Use of exhaust steam in 18
Dyes, French production 58
——Sulphur, Manufacture at Kingsport .. 639
——Tariff, Proposed amendments 70

E

Econometer, Arndt *291
Ecuador, Salt monopoly in 188
Edgewood Arsenal, Illustrated souvenir .. 469
Edgewood Arsenal, Walker, (N.) 386
——New commanding officer 636

EDITORIALS:
——Abolish duty-free imports of chemicals 201
——Alignment of the steel industry 451
——An appraisal of the American potash industry 306
——The blight of blatherskite rule 257
——Bolsheviks and research 450
——Capacities well aligned in the iron industry 51
——The Chemical Foundation and confiscated German patents 554
——Chemical industry and the Victory Loan 370
——Chemistry, metallurgy, and the high cost of living 371
——Cinematic micrography 499
——Commodity values and construction work 307
——Debating price mobilizing industry. 259
——Dislocation of the copper industry .. 145
——The duration of prosperity 611
——An engineering opportunity—the by-product coke oven 2
——Faith in our friends and allies across the Atlantic 50
——Favorable prospect for water-power legislation 202
——The first great step 554
——German chemical patents take on new aspects 258
——The gold producer and political economist 1
——Government control of markets 499
——Hard times for inventors 202
——Has heat treatment been demonstrated? 449
——Iron and steel in last year of war ... 5
——Iron and steel production in 1917 203
——The iron map of Europe 99
——Metallurgy and civilization 258
——The metallurgy of copper in 1918 4
——Minerals Separation wins doubtful victory 609
——National integrity, personal responsibility and the Victory Loan 449
——A new view of gas warfare 145
——Nitro-aromatics vs. nitroglycerine ... 306
——An opportunity for co-operative research 498
——The outlook of the optimist 49
——Pan American engineering literature. 1
——The passing of a friend 369
——A penalty on Western residence 553
——The philosophy of buying at present high prices 370
——Post-war meetings of scientific societies 201
——Progress in zinc smelting awaits impulse from metallurgists 202
——Promise of progress in rubber research 610
——Proposed improvements in American patent procedure 146
——Railroads and industrial research ... 370
——Readjustment and resumption 555
——Research forbidden to railway companies 306
——A resolution of forces 371
——Restoring the dollar's value 147
——The rude awakening 497
——Scholarships in Sweden 498
——Scrapping war chemicals 97
——Scrutable in the penultimate 50
——Speaking of propaganda 257
——Sulphur patents are decreed invalid .. 259
——Teach engineering students how to study—first 98
——Validation of informal contracts 201
——Wanted: A guardian for the United States 369
——Warning! Beware the gas-mask! 305
EDITORIALS, *Continued*:
——The way to prosperity 450
——What of industrial opportunities in France? 97

EDUCATION:
——Americanization work by Colorado Fuel & Iron Co 529
——Business training for engineers 564
——Chemical Engineering, McKee, (N.) 503
——Industry, democracy and, Corliss, (N.) 208
——Mining schools in Nevada 148
——Vocational, In paper industry 185
Electrical Precipitators, E. E. Thum *59
Electric power production by states 617
Electrochemistry in its human relations, Tone 413
Electro-deposition plant, Laboratory, Hayward *240
Electrodes, For Cottrell precipitator 62
Electrons, Arrangement in atoms and molecules, Langmuir, (N.) 393
Electrostatic precipitation, Braley, (N.) 384
Elements, Chemical, Melting points of 351
Ellison gage, Zero point, Bacharach *246
Enameled steel, Blistering of, (N.) 181
Enamels, Simple chemical tests for, (N.), 181
Engineer as citizen, Symposium, Program 270
—— Report 377
Engineering Council, National Service Committee 114
Engineering research, Field 84
Engineering, "Wild," Wesson 512
Engineers, Business training for 564
England, Industrial research in 390
——Tungsten in, (S.) 594
Europe, War-time trip to, Parmelee *124
Evaporation of small spheres, Langmuir, (S.) 135
Exhaust steam at high back pressures, Field 18
Explosives, Nitro-aromatics in 311
EXPORT STATISTICS:
——Digest, Chemical Alliance 295
——Caustic soda, Dec., 1918 219
—— Jan., 1919 334
—— Feb., 1919 492
—— Mar., 1919 593
—— April, 1919 617
——Copper, Jan., 1919 334
—— Feb., 1919 492
—— Mar., 1919 593
—— April, 1919 617
——Glycerine, Dec., 1918 219
—— 1918 288
—— Jan., 1919 334
—— Feb., 1919 492
—— Mar., 1919 593
——Gold and silver, 1918 136
——Lead pigs, bars, etc., Dec., 1918 295
—— Jan., 1919 400
—— Feb., 1919 492

—— Mar., 1919 644
Extraction, Computation of 224

F

Ferro-alloys, At Heroult 613
——Production costs 636
FERROMANGANESE:
——Adding in ladle 52, 53, 501, 612
——Analysis of 53
——At Great Falls, Mont 7
——Blast-furnace production, Royster, (N.) 215
——Eliminating phosphorus and sulphur, Lonergan 245
Ferromolybdenum, Westling, (P.) 249
Ferrophosphorus, Webster, (P.) 249
Ferrosilicon, Johnson, (P.) 249
—— Furness, (P.) 249
Ferrotungsten in England, (S.) 595
Filterpress, Calculating capacity of 230
Firebrick, Improved furnace for fusion point, Lovejoy 538
Flakes in alloy steel *216
Flakes in steel, Styri *342, 478
——Correction *453
——Criticism, Feild 556
—— Reply, Styri 557
FLOTATION:
——Bradford preferential, Dean 372
——Colloids in, Reply to criticism 52
——Concentrates, Nodulizing in rotary kiln, Draper 621
——Concentrates, Roasting, Fulton, (P.) 86
——Effectiveness of 573
——Experiments on hardwood tar oils, Hawley and Ralston 586
——For the practical mill man, Moses .. 571
——Galena, From mixed sulphide ores, Read, (P.) 544
——Hand device for experiments, Coghill *537

FLOTATION—*Continued.*
——Importance of pure water..... 574
——Lead ores, Allen 169
——Oils from crude tar..... 341
——Plant at Ohio Copper Mill..... 6
——Preferential. Edser and Tucker. (P.) 597
——Recleaning concentrates 576
——Recoveries 571
——Recovering pulp from waste liquor by. (N.) 184
——Slime removal 572
——Sulphidizing 559
Foreign trade, Aids to..... 189
France, Chemical industry during war, Maoussa. .....56 (S.)
Frasch sulphur patents. Court decision. Mock and Blum 542
Fuel economy in boiler house. Kershaw. 176, *241, *291 637

FURNACE, BLAST:
——By-products. Gayley. (P.)..... 432
——Cement from slag. Bereslavsky..... 25
——Ferromanganese in. Royster. (N.). 215
——Gases, Dry cleaning. Barrett..... *359
——Potash from. Criticism..... 308
—— Reply 373
——Potash from gases. (P.)..... 432

FURNACE, ELECTRIC:
——General:
—— Problems. Yardley 212
—— Large vs. small..... 374
—— Temperature uniformity in. Ferguson 283
—— Transformers for *600
——Various Designs:
—— Northrup induction. Theory. (N.) 381
—— Resistance, Granular carbon, For fusion point of coal ash. Lovejoy 538
—— Vom Baur *488
——Products:
—— Calcium Carbide at Muscle Shoals. 11
—— Cyanamide at Muscle Shoals..... 13
—— Ferro-alloys at Heroult..... 613
—— Ferromanganese 7
—— Ferromanganese. Eliminating phosphorus and sulphur. Lonergan.. 245
—— Ferrosilicon, Furness. (P.) 249
—— Molybdenum, Escard. (S) 645
—— Pig and sponge iron at Heroult.. 613
—— Pig iron, British Columbia....206, 630
—— Pig iron. Turnbull 178
—— Silicomanganese. Kluzh. (N.)..... 388
—— Steel, Armor, Nickel-manganese.. 618
—— Power costs 74

FURNACE, OPEN HEARTH:
——Manganese alloys used in. Hoyt. (N.) 215
——Refractories, Basic. (N.)..... 213
——Water cooled. Coffin. (N.)..... 213

FURNACE, MISCELLANEOUS:
——Caustic *65
——Cermak-Spirek. Mercury..... 34
——Bustamente, Mercury..... 33
——Gas-fired caustic pot furnaces..... 68

Pan American Engineering Literature

LA INGENIERIA INTERNACIONAL, the tenth member of our family of engineering magazines, will soon be issued in the Spanish language under the combined efforts of the McGraw-Hill editorial and engineering staffs. We of the chemical and metallurgical realm have especially wished to meet, understand and have greater communication with our neighbors to the South. While it is a fact that CHEM. & MET. has many readers at present in South and Central America, the Philippines and Spain, nevertheless the only efficient way of immediately realizing the much talked of Pan American Union in the engineering field is to break all fetters of speech and print in the most convenient language for our readers. For four and a quarter centuries, Spanish navigators have planted their language in many large but dispersed parts of the world. The general demand for a high class united engineering periodical adapted to these rapidly developing countries has not been met. It is believed that the efforts of the thousand specialists in engineering and publication work now united in the McGraw-Hill Company will be of service to these great peoples.

The Gold Producer and Political Economist

WE HAVE sometimes speculated, as we have perused the technical journals of the year just past, as to how their contents will impress the historian who, fifty years hence, may be inquiring into the state of the art of the metallurgy of gold during 1918. We wonder whether he will conclude that the metallurgists of this day were all political economists or whether all our political economists were metallurgists. Perhaps his verdict may simply be that the pressure of war conditions had gone to our heads.

The gold industry has not been on a normal basis for some years. There is no doubt that it has been seriously ill during the past year, and that the illness is continuing. But if a patient's chance of recovery is determined by the number of physicians in attendance, we may predict a speedy cure. Everywhere the situation has been discussed by congresses, conventions, mass-meetings; the technical press has overflowed with articles on the subject, written by mine-owners, mine-managers, metallurgists, geologists—even editors; the remedy was to be found in bonuses, subsidies, tax-exemptions either direct or indirect. It has all been interesting—certainly; instructive—perhaps. But it has added nothing to the metallurgical achievements of the year.

Unquestionably the metallurgical development of first importance has been Crowe's process of precipitation

in vacuo. A process of pleasing simplicity—and simplicity has characterized most of the valuable inventions—it takes a step which, though clearly indicated years ago by the trend of minor improvements, nevertheless escaped the attention of other metallurgists. The elimination of oxygen from the solutions at the approximate moment of precipitation is readily accomplished. The necessary apparatus is inexpensive and the power consumption almost negligible. The resulting saving of precipitant may be, we are informed, as much as 30 per cent.

But the various steps in the cyanide process are so inter-related that the possibilities resulting from the application of this process do not stop here. Thus, as the reduced amount of precipitant naturally leads to improvement in the grade of precipitate, we may speculate as to the probable evolution of refining methods. As we suggested a year ago, the electric furnace may appear in regular practice as a result of these changed conditions; on the other hand, the possible revivification of refining by distillation and recovery of the zinc from the precipitate seems more remote.

Again, although the process benefits in a measure both zinc-dust and zinc-shaving precipitation, its effect will be to improve the relative position of the former in popular favor. Ten years ago the dust method failed of establishment in South Africa, primarily because it could not, in the then state of the art, compete with shavings in the precipitation of a very dilute solution. It seems possible that, reinforced by the Crowe process, a different verdict will be given if the case is reopened.

This, too, is rendered more likely by the continuing development of American zinc-dusts of superior quality. Several such dusts, regularly marketed to-day, are consistently better than the best Silesian dust of 1914 and earlier. Here is one permanent gain for American industry.

Almost simultaneous with the advance in zinc-dust precipitation in America has been a successful development of charcoal precipitation by EDMANDS and MOORE, at the Yuanmi plant in Australia. The precipitating action of various forms of carbon has been for many years a subject of discussion, and we believe it to be the generally accepted conclusion that the actual work of precipitation is done, not by the carbon directly, but by adsorbed gases. This view is supported by the fact that graphite is without action. The very recent campaign for peach-pits and similar shells of vegetable origin, to be converted into charcoal for use in gas-masks, is an interesting illustration of the variation of this property in different charcoals. In the discussion of EDMANDS' paper before the Institution of Mining and Metallurgy, this question was touched upon, and it was emphasized that the successful work at the Yuanmi might have been due, in a measure at least, to the use of charcoal made from mulga—an Australian hardwood.

The precipitating action of certain carbonaceous rocks has often been a source of difficulty in cyaniding, preventing satisfactory extractions through the premature precipitation of some dissolved gold. Work by FELDTMANN and WARTENWEILER on West African ores has shown that such gold may be redissolved in sodium sulphide solutions, and an ingenious process has applied this principle. It seems to have possibilities in other localities.

The special applications of cyaniding to silver ores have experienced no additions during the year, but the work being done in Colorado, under the direction of the Bureau of Mines, will be awaited with interest. This investigation looks to the beneficiation of the manganese-silver ores, so frequent in occurrence and so generally refractory, and we understand that it offers excellent promise.

Flotation, as affecting gold and silver metallurgy, remains as it was a year ago. Mechanically, too, the year has little to record. Practically no new construction has been coming forward, and no new light has been thrown on the crushing problem. BLOMFIELD published an able paper in discussion of Golden Cycle milling, and the data given of the performance of the bowl classifier—the latest of the Dorr machines—suggest that it will have a considerable field of usefulness.

The cyanider is interested in the future of the great nitrogen-fixation plants proposed for war purposes. He is looking to these, and perhaps also to the more serious efforts to produce cyanide from cynanamide, for a considerable reduction in the price of cyanide and for a little healthy competition in the business.

An Engineering Opportunity— The By-Product Coke Oven

THE chance to note the possible improvements in chemical engineering were never greater than at present. Of course, most of us think first of the opportunities naturally furnished or suggested by the sudden change from war to peace—military peace—though it is possible that commercial war of natural competition will be more strenuous than ever.

Among the matters of first importance are the ever vital questions of power and fuel; for, as FRANCIS BACON observed, with his marvelous insight, "As the soul is the former of forms and as the hand is the instrument of instruments, so fire is the helper of helps." PROMETHEUS was well called the friend of man, when he is feigned as bringing down fire from heaven to give to humanity; and well might JOVE himself be jealous of this incomparable gift to his creatures. But it is surprising that we of the twentieth century should be so backward in using and applying this "helper of helps" with so little efficiency and economy.

Among the great developments of the age there may be well counted the "by-product coke" industry. There are several makers of plants that are gradually but surely replacing the old emergency "beehive ovens," which in all candor were devised solely for the purpose of making coke. The iron and steel industry must have coke, and the beehive furnished it; and to the beehive must be given the credit of building up the iron and steel business.

But with the advent of the varied savings of the by-product oven the question still comes up: Why do not the designing engineers go further and study the actual conditions of the by-product process, with its marvelous production and with its marvelous waste? Let us look at it broadly.

It is now a fact, practically recognized by most of the leading gas engineers, that the carbonizing of coal to coke is a process in itself, which, when the coking temperature once is reached and maintained, ought to go on of itself, as though it were almost neutral in its

heat absorption or possibly actually exothermic. This means that, when the coking temperature is once reached, the process ought to go on with the expenditure of no more heat; it ought to be practically automatic. But what do we actually see?

The facts are that the ordinary by-product oven is a gas machine that uses half of the gas produced to maintain the process; that the huge mass of ovens and retorts, with their heating chambers and regenerators or recuperators, is one big, wasteful heat-radiator—and a very wasteful radiator. One cannot step close to the oven pile with any comfort. It is simply one big heat sieve, throwing off good energy—up the stack, and out at the sides, and in all directions. Moreover, the time element is something that is but poorly camouflaged under the enormous profit-and-loss account that seems to carry the whole scheme—the time lost is something that the twentieth century engineer would shudder at if it were put up to him for a first consideration; and we are forced to the conclusion of the farmer who settled all questions of farm economy by saying, "What's the use of time to a hog?"

This wasteful heat-hog of the by-product oven must have come from some such origin as the Hunnish character of some of the names suggest. No Yankee would ever have dared to try to put any such thing across. Only a so-called civilization that was reckless of the time element would ever have had the gall to plan for a carbonization process that takes the best part of a day to coke one oven; and the trick of merely multiplying this by "*x*" or "*n*"—this does not excuse the monumental blunder of the first design, nor its subsequent foisting off on the American public. The only wonder of it all is that it ever happened. It looks as though some of us ought not to be allowed to run around loose without a guardian to watch us and to see that we did not take up with the first "gold brick" that was offered us.

And let us see wherein this wasteful process is wasteful. Here let us notice that the by-product process in general is one of marvelous perfection of well planned detail, so marvelous in its exactly calculated wealth of detail that it is itself a wonder of invention. This well planned process is apparently carefully designed; but it is designed on the wrong plan. It reminds us of the wonderful design that Mother Nature showed when she spent so much time and effort on making the insect creation—a creation that came near rivaling the mental and physical powers of man, but it was designed on the wrong anatomical plan. So of the by-product plan; it is wrong in one—one at least—small feature; that is the heating wall of the oven where the carbonization is done. This heating wall is composed of bricks or the equivalent, which will convey the heat through the wall —in time, that is, the best part of a day.

Think of it! Trying to force the heat necessary to carbonize the coal to coke—and it cannot be great—through some six or eight inches of earthy material. For, to illustrate the case of one of the better grade of ovens, the walls are composed of silica brick six or eight inches long; and the heat must travel endwise through the entire length of the brick to reach the coal. It is no wonder that this heat-conduction process must take nearly a day. It is here that the inventor has a chance to improve on the silica-brick heat-conductor.

To be sure, it is well known that the heat-conductivity of the silica brick is considerably greater than the conductivity of the fire-clay brick that were used for the oven walls earlier; but that does not evade the main question of the time loss of the general process. Neither does the contention of some of the engineers answer the time-loss matter; in that the heat-conductivity of the coal and coke in the inside of the oven is stated to be so slow that the slow heat-conduction of the silica-brick walls can keep up with it.

The facts of the heat-conductivity of the coal or coke in the inside of the oven are not well worked up; but the best authority on the subject tells us that there is no doubt that the heat-conductivity of the coal or coke is immensely greater than the heat-conductivity of the silica-brick walls; though one must consider the heat-insulating power of the porosity of the coal or coke, this latter element causing the heat-conductivity to be retarded about in direct ratio to the porosity. But even then it is fair to assume that the practical heat-conductivity of the average coal or coke must be immensely greater than what it utilized.

There is a strong suspicion that the attempt of some of the gas engineers to cover up this point indicates that they are gradually becoming aware that there is something fundamentally wrong with the design of the by-product coke oven. Moreover, the very necessity of driving the heat-conduction of the silica walls of the oven is so strenuous that the whole process is conducted at temperatures much greater than are necessary for the carbonization of coal to coke. To be sure, the quality of the coke produced—and it must be noted that the purpose of the by-product coke oven is in the first place, generally, the making of coke—is said to be better and more uniform than that of the usual beehive oven; but this is the natural result perhaps of the great care and attention that have been given to this phase of the process. It does not follow that it is impossible to make good coke at lower temperatures or in shorter time.

But the main thing to note is that it ought to be possible to find some material of better, much better, heat-conducting power for the oven wall, that shall replace the silica brick, with its sluggish time factor. Some of us think that we have found some such substitute. The matter is being aimed at, and in due time will be developed; but the wonder is that this marvelous opportunity should not have been studied long ago. The wonder is that such a peculiar case of wrong invention as the silica brick, for this purpose, should ever have had its day. To be sure, it is just like the history of invention that such experiences should happen; but once the matter is brought out into the light it ought to be a plain case of improving it.

Of course, the secret files of many of the large companies might be able to disclose many interesting facts; and we may, in time, find out why this case has been allowed to lie dormant. It is suggestive and will prove interesting matter for the later historian of chemical and metallurgical progress. It may well be that the apparent facts of the case are opposed to any revolutionary changes; it may well be that some fool inventor may find the solution, just because he did not happen to know that the desired improvement is impossible, and so simply may go ahead and find what we are looking for. But whatever the issue of the case, the general

question is worth while studying; for it is patent that we must soon find a more economical method of making gas in such quantities as has not yet been dreamed of. For instance, it ought to be possible to plan for the day when no solid fuel shall be carried into such a congested place as Manhattan Island, for instance; but when all the fuel shall be piped over as gas, or, better, as electricity. It ought to be possible for the time to come when no coal shall be carried from the mine, but when it shall be turned into gas (or electricity) directly at the mine mouth. Such dreams are only the precursor of the reality; for, other things being equal, whatever is rationally thinkable, that is mechanically possible.

Meanwhile, of course, there are possible ways of saving much of the heat now wasted, from the constant radiation in all directions, from such heated masses as by-product ovens, glass pots and the like. It ought to be possible to recover much of this waste by a simple regenerator jacket about the mass, or about its most exposed parts; but the main suggestion is worth pondering; it will arrive in due time, with full realization.

The Metallurgy of Copper in 1918

COPPER production in the United States, steadily climbing from the minimum established at the outbreak of the war, reached a peak in the summer months of 1917. Totals for 1918 will exceed those of 1917 only beacuse operations were paralyzed during the second half of the previous year on account of an epidemic of labor troubles. As to labor, many scattered incipient outbreaks fortunately were speedily adjusted, and so the year 1918 has been one of apparent quietude and unprecedented wage scales. The steadily decreasing volume and efficiency of labor have made it increasingly difficult to supply the war orders even at the good prices current. Naturally there were instituted but few notable additions to smelting plant—it was difficult enough to keep the old capacity satisfied. This combination of circumstances has forced many mines to retrench on exploratory work and skim the cream of their deposits, leading to a "worked-out" condition which may prove disastrous in a falling market, and certainly will require the most expert technical knowledge to bridge. It is yet too soon to appraise the effect which the return to peace will have upon the price and requirements of the metal and of the commodities and labor needed for its production. The utter absence of demand for copper may reflect a widespread opinion among the consumers that the prices of copper, as well as of other things, are war-inflated and due for a drop.

More than ever it was incumbent upon the mill superintendent to recover all the copper possible from the ore sent to him. The use of flotation, either as a substitute or adjunct to gravity concentration, had already been successfully established and had greatly improved the recovery on properly sized sulphides. How to concentrate the unfloatable copper oxides, carbonates and silicates in the tailings has received much study during the year, and several large mills have attacked their individual problems successfully. Hydrogen sulphide, alkaline sulphides and sulphur dioxide are favorite reagents added to sulphidize a sufficient area of the oxide particle so that it may float. Less soluble silicates, partially oxidized ores and tailing piles may perhaps better be first leached with sulphuric acid, when the cleaned sulphides remaining float very cleanly. Enormous and increasing quantities of copper are being recovered by such schemes at the Hurley, Hayden, Miami, Garfield and Anaconda, and have been responsible for corresponding increases in output of by-product sulphuric acid.

Adequate roasting is the kingpin of successful smelting. This has been demonstrated again at Humboldt, where the installation of a modern and ample roaster department increased reverberatory furnace tonnage so largely as to shut down the blast furnaces; the grade of matte was also increased and properly controlled, with a corresponding reduction in converter work and costs. Experiments have shown that sulphur burns out of fine concentrates as they drop from hearth to hearth at a much higher rate than while being rabbled. Since we are now able to cope with the dust problem, roaster evolution may well be toward high shafts with many narrow hearths, so that the ore will spend a larger part of its time surrounded by heated air. It has also been recognized that the fuel ratio in reverberatory smelting depends directly upon the temperature of the calcine charged. Therefore, efforts have been made to reduce avoidable radiation losses by insulating the hoppers and making a quick transfer.

Metallurgists at Douglas have made much admirable progress in their reverberatory practice. STOUT, at the Copper Queen, doubled the size of the uptakes in order to avoid choking the draft at the skimming end of the furnace, and found that he was able to burn a largely increased quantity of fuel, with even greater efficiency. COLE and JACKS at the Calumet and Arizona, following in his footsteps, found that the excessive heat at the uptake melted down the furnace arch very quickly. In trying to avoid the large losses in time and money caused by such failures, they controlled and shortened the fire zone by proper air-inlets around the burners and through the arch. Almost any step which will increase the concentration of heat appears to be desirable:—a flat verb with large flue areas, larger oil nozzles blowing superheated oil with compressed air, roof ports, double banks of burners, hotter calcine. For best results, then, an explosive flame burning fuel at the maximum rate should fill the fire-end of the furnace only as far as the last charge-hole. STOUT even advocates drawing off the gases at the middle of the furnace, converting the skimming bay into a large settler, independently heated and charged with sufficient pyritic material to wash the slags very thoroughly and thereby reduce their copper content.

By properly adjusting the length of flame and increasing its combustion rate, these Arizona plants have achieved remarkable furnace capacities and fuel ratios. Thus, the best daily average for the 19 by 100-ft. reverberatories at the Calumet and Arizona was 400 tons of calcine at a fuel ratio of 0.75 barrel oil per ton. Since revising the burning-practice these figures have increased to 800 tons at 0.62 barrel. The huge 38 by 130-ft. furnace at El Paso has done even better with 850 tons at 0.61 barrel, and has attained a remarkable daily maximum of 964 tons. The best fuel-ratio will occur when charging calcine at the maximum heat—

Capt. STOUT has set his ambition at 0.45 barrel of oil per ton of calcine charged at 1150 deg. F.

Excellent furnace practice is not confined to these oil-burning reverberatories. Thus at Garfield, by careful adjustment of combustion and charging practice, it has been possible to smelt regularly 600 tons of calcine daily with but 15 per cent of powdered fuel, while a larger furnace at Anaconda cleans 500 tons of converter slag by melting an equal quantity of partially roasted concentrates with a fuel expenditure of 8 per cent.

The question "Oil versus Powdered Coal" is of course largely decided by relative costs; it is significant, however, that plants so far from coal fields as Hayden, Clarkedale and Tacoma have recently installed powdered-coal systems.

Basic-lined converters of extraordinary size have proved their superiority wherever a sufficient quantity of matte is available to keep them in blast. Operating on 16 per cent matte, as at Anyox, they exemplify the principles of pure pyritic smelting. The use of the silica gun has more than fulfilled expectations, uniform operations and temperatures have lengthened the interval between lining repairs and allow the production of a slag higher in silica. In case converter slag is hot-charged into reverberatory furnaces, it is then more nearly of the same specific gravity and will diffuse somewhat more readily into the reverberatory slag. This may be of considerable advantage in the economical recovery of its copper content.

Adequate flue and chimney capacity is evidently essential for the best developments in reverberatory smelting. The number of Cottrell plants and high stacks recently under construction (notably El Paso, Hayden, Humboldt, Anaconda and Tacoma) indicates that many metallurgists agree with O'GARA'S ideas on smoke dissipation. One is justified in spending money only for the recovery of the actual values in the gas; the remaining more or less dangerous constituents can best be eliminated by means of stacks discharging smoke at proper temperature and proper elevation so that it will be reduced to an innocuous dilution before reaching the ground.

Iron and Steel in Last Year of War

THE salient feature of war time control of the iron and steel industry was this, that before all the direct war needs and the requirements of the "essential" commercial industries were provided for there was no steel left. Another feature was that when complete lists of all the industrial activities that were adjudged helpful toward winning the war were drawn up there were very few industries that consume steel that were left out. Two things were proved, first, that in waging modern warfare nearly all industries are needful, and second, that steel is the backbone of nearly all industries. No defined industry of any importance was omitted in the distribution of steel, but certain "purposes" were recognized, leaving other purposes unrecognized. The manufacture of passenger automobiles for public sale was not recognized, but the automobile shops were given orders for passenger vehicles and trucks for war use. Building for civilian purposes was not recognized, but there was much building for war purposes.

The condition that resulted from active participation in the war was one that was not dreamed of even by the most far-seeing when the country declared war. Then the trade engaged in speculation as to what part of the steel output would be required for war purposes, and estimates that placed the proportion at one-third were among the highest. The steel trade, usually gifted with keen vision, thought of steel demand in war time as made up of shell steel, gun steel and similar items. From such a viewpoint, all our steel could not possibly be needed, for in terms of ingots our capacity was nearly 45,000,000 tons, while the Central Powers commanded only a trifle more than 22,000,000 tons, and the Entente Allies, with the aid of steel imported from the United States, had hardly commanded as much more. Thus, apparently, only a small part of our steel would be required to upset the balance. The error lay in failing to recognize that everything possible was to be marshaled. Public service corporations would be expected to render the fullest possible service, and thus would need steel, and so with railroads, machine shops, agricultural implement factories and very nearly all the mines of every description. Instead of plowshares being beaten into swords, more plowshares were wanted.

What did the steel industry do? The division may not appeal to the purist, but the industry's output of steel may be considered from three viewpoints, of quantity, of character and of quality. As to quantity, the industry produced about 42,000,000 gross tons of ingots in 1918, when its capacity, given favorable conditions in all respects, was fully 47,000,000 tons. As to character, the industry showed a flexibility that had never been recognized in it, for it converted an altogether unexpectedly large percentage of its steel into plates, it turned out enormous quantities of shell steel through rolls that had never been thought of in connection with such sections and it made tin plate at a wonderful rate. As to quality, many mills produced steel shell and other steel of fine quality when previously they had never thought of making anything but the commonest kind of steel. The industry produced wire to tensile strength specifications that at first made the more sanguine stand aghast. It produced seamless and welded tubes of better quality than ever before. It produced and rolled electric steel for helmets that were admitted to be the best on the battlefront.

There is no doubt that the steel industry's capacity in 1918 was fully 47,000,000 tons of ingots, that estimate being based upon actual production in 1916, plus allowances, on a conservative basis, for new construction. About 2,000,000 tons output was lost in January and February through the railroad breakdown, affecting the steel industry chiefly through short supplies of coke. The influenza epidemic curtailed output in October and November, perhaps by half a million tons. There was some relaxation after the armistice, production being slightly less than would have been the case if the war had continued. Throughout the year there was a shortage of labor, and there were various minor difficulties as to the securing of supplies and equipment, that exercised some influence in limiting production. An important factor was the shortage of scrap of good quality, such as conduces to heavy open-hearth furnace tonnages.

The American steel industry, however, emerges from the war with its capacity increased about 40 per cent.

Western Chemical and Metallurgical Field

Ohio Copper Mill

THE Ohio Copper Mill at Lark, Utah, was completed late in 1909, at a cost of about $1,300,000. Erected by Heinze interests, it was one of the three big mills in the Salt Lake region treating disseminated copper ores from Bingham canyon. Unlike the ore from the Utah Copper and Boston Consolidated ground, it handled a hard, very tough quartzite slimming less in crushing than the softer porphyries. Since some rather high-grade ore from the upper levels was to be treated, Hartz jigs were installed to concentrate the coarse material delivered by Blake crushers and intermediate rolls. Jig tailings, together with coarse spigot discharges, were reground in Chilean mills. The bulk of the plant consisted of hundreds of tables; high-silica concentrates made on primary tables were recleaned on secondary tables designed to increase the copper content, while the dewatered slimes were concentrated on more Wilfleys, whose overflow was passed over slime tables before being finally discarded.

This plant was very carefully designed after large-scale tests on the ore, and incorporated the best ideas of the time. Operating on a low-grade ore, the concentration ratio reached a value of 20 to 1. Some 8 million tons of ore were treated before the steadily decreasing ore content caused the abandonment of gravity concentration.

At the present time practically all the original equipment is being removed to make way for a more compact flotation plant. Three 600-ton units are now in operation in the south end of the building, and work is well under way on two additional sections; the total capacity is thus increased while needing less than ⅔ the total building space. Fortunately, the disastrous fire occurring last August burned only the north end of the ore bins—which is the only portion of the plant containing much wood in the superstructure—and interfered but little with operations of the modernized sections. The destroyed bins are being rapidly replaced with reinforced concrete construction.

As compared to the older flow sheet, the flotation plant is simple and direct. The coarse crushing plant, capable of crushing 3000 tons per day, consists of one primary Blake and three sets of 60 by 24-in. Garfield rolls in closed circuit with 4 duplex whip-tap screens, screening to ¾ in. Until such time as the above arrangement is completed, the ore is being broken to 1½ in. in two Blake crushers before being sent to the fine-ore bins. The ¾-in. product will be washed in a locally-made drag to remove the natural slime in the ore. Primary grinding for each unit is done in the first of two 8-ft. by 36-in. Hardinge mills, which discharges into a Dorr duplex drag classifier. Oversize from the classifier enters the second Hardinge, operating in closed circuit. The overflow from the Dorr classifier goes direct to a 16-cell M. S. flotation machine.

Flotation tailings are at present passed over Wilfley tables to recover coarse sulphides, but due to the high recovery of the flotation machines they will probably be discontinued. A pair of Janney machines are being installed in each unit to clean up the M. S. concentrate. Flotation concentrates from three sections are dewatered in three 42 x 10-ft. Dorr thickeners, whose pulp feeds a pair of 12 x 12-ft. Portland filters. Lowden driers bring the moisture in the filter cake down to 15 per cent.

Original difficulties in maintaining expected extraction have been overcome by A. H. HELLER, mill superintendent, by removing the natural slime occurring in the ore, which exerts an influence on recovery out of all proportion to its absolute quantity. As previously noted, this is effected by washing the fine ore in a locally made drag, capable of handling material up to ¾ in. without difficulty. Careful attention to the relative proportions of coal tar and pine oils is necessary so that no unoiled particles of sulphides appear when panning the tailings. The profitable treatment of such low-grade ore, mined by expensive underground methods during times of high commodity and labor costs, is an achievement of more than ordinary merit.

The Joplin Zinc Situation

AT THE instance of POPE YEATMAN of the War Industries Board, a committee from the Joplin Ore Producers' Association met with a committee representing the zinc mining and smelting industry in its relations with the government during the middle of October, and formulated an agreement effective for three months which was designed to reduce the wide "spread" between the price of metal and ore which has recently caused a sharp curtailment of mining. According to W. B. SHACKELFORD, a member of the conference, the agreement was based on the following figures:

Cost of producing 60 per cent. concentrates, including royalty: $60 per ton.

Cost at gas smelters, not including risk of failure of fuel supply: $23.50 to $26 per ton.

Cost at coal smelters, not deducting return for acid: $32.50 to $34 per ton.

Average cost of smelting, basis: zinc at St. Louis: $30 per ton.

Smelter recovery: 83 per cent.

Thus it was found that if the spelter market were quoted as $8.75 per hundred pounds and the ratio between metal and ore were at 6.52, the mine and smelter would both receive about enough to pay their expenses. Therefore it seemed proper to adjust a sliding scale such that when the spelter market was quoted at $6 per hundred the price of 60 per cent ore would be 6.80 times the price of zinc, or $40.80. The ratio decreases by one hundredth for each tenth of a cent advance in zinc per pound; thus, at a 10-cent market, the ratio is $6.80 - 0.01(10.0 - 6.0) = 6.40$, and the price of ore would be 10×6.40 or $64, subject to the usual premiums and penalties for composition. To stabilize the market the agreement further specified that the smelters would obligate themselves to absorb a certain amount of ore weekly for the period of the agreement.

In order for the plan to become effective it was necessary for practically all the smelters handling Joplin ore to sign the agreement. About 70 per cent of the smelter tonnage signed, and nearly all the mines in the district became a party to the agreement. During the

first week, the signatory smelters purchased 2400 tons at the agreed price of $55.67, while outsiders secured 1300 tons at from $52.50 to $55. During the week ended Nov. 17, however, many buyers remained out of the market, and but 2300 tons were purchased at the agreed price of $54.53, while 1700 tons were picked up at prices ranging down to $45. Unfortunately the agreement contained no stipulation binding the miners to refuse offers at less than the agreed price, and many in financial straits were forced to realize on their concentrates.

Joplin ore producers therefore voted on Nov. 16 to curtail or suspend operations in view of the very large accumulation of unsold concentrates, leaving the situation in the hands of "outlaw" miners and buyers.

Suspension was contingent, however, upon obtaining signatures of 60 per cent of the production, which was not forthcoming. Smelters then agreed to state the weekly amount of ore required, which would then be allocated among the mines. Completion of storage warehouses for 150,000 tons of ore is also expected to stabilize the situation materially, since miners could borrow 90 per cent of value on warehouse receipts. Meantime spelter is dull and weak and the situation is disarranged by sales of a large amount of concentrates at the market by a big company on telegraphic orders from the owner.

Curtailment and shutdowns are now the order of the day for higher cost producers; in fact, the sheet ground region near Duenweg is practically abandoned at present.

Ferromanganese at Great Falls, Mont.

OPERATION of the ferromanganese department at the Great Falls plant of the Anaconda Copper Mining Co. began about the middle of September, when the first of the electric furnaces was started. The proposed plant was briefly described on page 391 of our issue of April 15, 1918, construction having started early in March.

Each of the furnaces consists of an open-topped shallow brick shaft, 28 x 14 x 11 ft. in outside dimensions. The outer walls are of red building brick with an inner firebrick lining. This shaft has a tamped lining composed of dead burned magnesite with pitch as a binder. The tamped lining is 3 ft. thick in the bottom and is brought up the sides to a point about 18 in. above the tap-hole level. The inner dimensions of the shaft at the middle section are 22 x 9 ft. The furnace is 6 ft. deep. The furnace is operated on 60-cycle, three-phase alternating current. Two 24-in. round electrodes are used in a common holder on each phase. The electrodes are spaced 6 in. apart in the holders and the pairs about 5 ft. on centers.

Electric power is delivered at 100,000 volts from nearby hydro-electric plants of the Montana Power Co. and is transformed to furnace voltage, 115 volts, in two steps, 6600 volts being the intermediate point. Each furnace is equipped with one General Electric polyphase transformer rated at 5630 kva. Each furnace has a rated power consumption of 3500 kw. and an output of 18 tons of 80 per cent alloy daily.

A very considerable quantity of carbonate ore of the following approximate analysis has already been blocked out in the upper levels of several of the Butte mines belonging to the Anaconda Copper Mining Co.

Moisture	1.82 per cent
Manganese	35.89 "
Silica	9.34 "
Iron	2.0 "
Alumina	2.15 "
Magnesia	2.50 "

Six parts of this ore will be reduced by two parts of a local bituminous coal; the mixture will also contain about one part limerock to flux the impurities in the ore and coalash. Sufficient iron ore will also be charged to bring up the iron content in the resulting metal. The proper mixture is delivered to charge hoppers by overhead crane, the furnaces themselves being built in the north end of the main smelter building opposite the abandoned copper blast furnaces.

Metal and slag are tapped together into pots. The waste slag is skimmed and the metal cast by a casting machine formerly in use for casting copper.

E. S. BARDWELL, superintendent of the ferro-alloy department of the Anaconda company, hopes to have the five furnaces running to capacity within six weeks, when he will have the world's largest ferromanganese plant in operation. About seventeen pounds of 80 per cent ferro is required to deoxidize a ton of open-hearth steel; thus the daily production of ninety tons at Great Falls will annually satisfy the requirements of 3¾ million tons of mild steel. An idea of the importance of this one plant may be had from the statement that its production will care for 8 per cent of the entire yearly production of steel ingots in the United States and will release six or seven 5000-ton ships from transporting Brazilian manganese ore to this country.

Iron and Steel Metallurgical Society

THE need for a metallurgical society exclusively confined to the metallurgy of iron, steel and their alloys has been keenly felt for a long time. Metallurgists prominently connected with this branch have from time to time expressed themselves to this effect. Recently several of them discussed the matter in a definite way at a meeting held in the Fort Pitt Hotel, Pittsburgh, when the formation of a society was decided upon. Its aim and object is the promotion of the arts and sciences connected with the metallurgy of iron, steel and their alloys.

A committee to consummate the plans of this meeting was appointed, of which Mr. D. L. MATHIAS of Mackintosh, Hemphill & Co. was selected as chairman, who are taking steps to materialize the society. Before the society can be a real force, the active co-operation of those eligible for membership will, of course, be needed.

The committee will be pleased to answer inquiries and furnish information to those interested.

Operation at Grand Forks—A Correction

In our issue for Oct. 15, 1918 (Vol. 19, p. 606), the statement was made in error that the Grand Forks smelter had been shut down. Mr. W. A. WILLIAMS, supt. of smelters for the Granby Consolidated, informs us that the plant continues to operate three furnaces, since smelting at this point has been successfully maintained irrespective of the grade of ore so far available.

Muscle Shoals Nitrate Plant

Description of the Largest Synthetic Nitrogen Works in the World—Cyanamide Process—Lime and Coke, Carbide Furnace and Milling, Liquid Air, Oxygen and Nitrogen, Ammonia, Catalytic Oxidation and Nitric Acid Departments Detailed

By ANDREW M. FAIRLIE
Consulting Chemical Engineer, Atlanta, Ga.

MILITARY explosives may be divided, according to the uses to which they are put, into two classes: Propellants for hurling projectiles, and high explosives for bursting the bombs or shells. Both classes are nitrogen compounds made from nitric acid or ammonia or both. The propellants are made by treating cotton or glycerin with nitric acid, and the bursting explosives are made by treating toluol, benzol or ammonia with nitric acid. The names of the three most important bombing or shell-bursting explosives are trinitrotoluol (TNT), trinitrobenzol (picric acid) and ammonium nitrate. Since the cost of either TNT or picric acid is about two and one-half times the cost of ammonium nitrate, it became plainly important, soon after the United States entered the great war, to increase the supply of nitrate of ammonia in this country as rapidly as possible.

At the same time it became distressingly evident to the chemists of the country that this nation was entirely dependent upon a foreign country for its supplies of the only chemical from which nitric acid could be made in quantity. This chemical—nitrate of soda—had to be imported over thousands of miles of ocean from Chile, and it was forcefully realized that if this country should become involved in war with any nation which could gain control of the seas and thus cut off our supplies of nitrate of soda, we would be unable to make ammunition, and hence we would be at the mercy of a foreign power. Added to this was the knowledge that a large fleet of ships was required to transport from Chile the large tonnage of nitrate of soda so urgently needed for munition-manufacture, ships which were sorely needed for the transport of troops and supplies to France and could not well be spared for the long journey to South America. Furthermore, the manufacture of nitric acid from nitrate of soda requires the consumption of large quantities of sulphuric acid, of which there was already a serious shortage.

Steps to Overcome Vulnerable Position

In this emergency and with the realization that the output of a plant for the manufacture of nitrates could be used in time of peace for fertilizers as well as in time of war for munitions, the Ordnance Department determined to correct the vulnerable position of the country and to render the United States independent of foreign countries for the manufacture of nitric acid and nitrates.

Since in this country no extensive beds of natural nitrates exist, artificial nitrates had to be made, and the only existing sources were (1) the gases of the by-product coke ovens, and (2) the nitrogen of the atmosphere.

The capacity of by-product coke ovens had already been doubled since August, 1914. The cost of construction of these ovens had risen to about two and one-half times the normal cost. To furnish the amount of ammonia needed from this source could have required another doubling of capacity, at an expenditure of money and consumption of valuable time which would have been intolerable. The only practical source of artificial nitrates appeared to be the unlimited quantities of nitrogen in the atmosphere.

In the fall of 1916, Dr. Charles L. Parsons, Chief Chemist of the Bureau of Mines, who had been sent abroad to investigate European methods for the fixation of atmospheric nitrogen, returned to this country and submitted his report.

Important Processes for Fixation of Atmospheric Nitrogen

The three most important processes in commercial use were known to be the arc process, the Haber process, and the cyanamide process. In the arc process air is blown through a flaming electric arc which burns the nitrogen to nitric oxide, and this is absorbed in water or milk of lime to make nitric acid or nitrate of lime. Its successful use has been limited to localitites such as exist in Norway, where enormous hydro-electric power can be generated at very low cost. There is no water-power site in this country which can compete as to cost of power generated with the Norwegian sites. The Haber process combines nitrogen and hydrogen, mixed in the right proportions for chemical combination, at a very high temperature and pressure, by means of a catalyzing agent, thus forming gaseous ammonia, which can be burned by passing through incandescent platinum gauze to form oxides of nitrogen, which in turn can be passed through towers sprayed with water to form nitric acid. The practicability of producing ammonia and nitric acid by a modification of the Haber process had already been a subject of investigation by the Nitrate Supply Committee of the War Department, and a plant using this process to be erected at Sheffield, Alabama, with a capacity equal to 22,000 tons of ammonia nitrate per annum, had been contracted for. This plant, known officially as U. S. Nitrate Plant No. 1, was being built under a Congressional appropriation of $20,000,000. It was also planned to test several other new processes at No. 1 Plant. However, none of the processes to be tested at Plant No. 1—not even the modified Haber process—had ever been operated successfully on a commercial scale[1] and could not therefore be fully depended upon; therefore, the Ordnance De-

[1]The true Haber process, said to be operating successfully in Germany, was not known in this country in all its details.

partment was unwilling to commit itself to the extension of any of these uncertain processes, and instead resorted to a consideration of the cyanamide process.

The Cyanamide Process

The dependability of the cyanamide process had already been proved by actual commercial operations over a period of years. Cyanamide had been manufactured continuously since 1909 at Niagara Falls, Canada, and since the outbreak of the war the plant there had had a capacity of 64,000 tons per annum. A considerable part of the cyanamide produced had been converted into ammonia since the early part of 1915 and had been used in producing ammonium nitrate for the Allies. A plant for the oxidation of ammonia, produced from cyanamide, to nitric acid had also been in continuous operation on full-sized equipment for more than a year. The patents for producing chemicals by the cyanamide processes were controlled by the American Cyanamid Co.

With these facts in mind the Ordance Department, in the fall of 1917, invited the American Cyanamid Co. to present some plan for the manufacture of ammonium nitrate on a large scale. The plan presented was for the manufacture of ammonium nitrate from air, steam and water, by means of the common materials limestone, coal and coke. One or more plants, it was shown, each complete in itself, could be built within twelve months to supply the entire quantity of ammonium nitrate desired. There was to be nothing experimental or untried about the project. All that would be required would be to reproduce, on any scale desired, the several elements of existing installations successfully operating. The cost of construction would be only a small fraction of the cost of building by-product coke-ovens of equal ammonia capacity.

At the request of the War Department the American Cyanamid Co. formed a subsidiary company, known as the Air Nitrates Corporation, to act as the agent of the United States Government for the construction and operation by the cyanamide processes of a plant at Muscle Shoals, Alabama, to produce 110,000 tons per annum of ammonium nitrate. This plant is known as U. S. Nitrate Plant No. 2, to distinguish it from Nitrate Plant No. 1, referred to above.

U. S. Nitrate Plant No. 2

Nov. 16, 1917, was the date on which it was decided to construct the new plant. The first carload of material was delivered on Dec. 20 the same year, and the first ground was broken on Feb. 16, 1918. Since then more than 20,000 men have been employed on construction of the plant. The site for Nitrate Plant No. 2 is on the Tennessee River at Muscle Shoals, in the northwest corner of the State of Alabama, between the towns of Sheffield and Florence. The nearest railroad station is at Sheffield, some three miles away, served by the Louisville & Nashville Railroad and the Southern Railway. The site occupies 2,200 acres, including a permanent town built to accommodate 12,000 people, composed of two communities, one for white people and the other for negroes. Temporary quarters had to be rushed first, however, for the thousands to be employed in construction work, and by May a mushroom city of 20,000, with lodgings, restaurants, offices, police headquarters, hospitals, motion-picture theatres, telegraph, telephone, electric light and sewerage systems and many other necessities and conveniences of modern urban life, covered the ground which had been growing corn and cotton or over which the native Alabaman had hunted the rabbit and raccoon the preceding fall.

Ten Operating Departments

The complete plant includes ten operating departments, each housed in one or more separate buildings, an office, shops, laboratories and other general service buildings. The important operating departments are as follows:

1. The power plant.
2. The carbide-materials department.
3. The carbide-furnace department.
4. The carbide-mill department.
5. The nitrogen department.
6. The lime-nitrogen department.
7. The lime-nitrogen-mill department.
8. The ammonia-gas department.
9. The nitric-acid department.
10. The nitrate department.

The entire plant is so laid out that beginning at the carbide-materials department, located some 3600 feet south of the Tennessee River, the main product of each department will proceed to the next department continuously from north to south, in the order named above. An exception to this rule is the nitrogen department, which, producing a material to be used first in the lime-nitrogen department, has been placed far to the east of the lime-nitrogen building, for reasons to be explained later.

The Power Plant

Ultimately, power for Nitrate Plant No. 2 will be furnished by the large hydro-electric plant to be constructed by the Government on the Tennessee River at Muscle Shoals. This proposed hydro-electric plant will form the subject for a long story in itself. It will suffice here to say that the development of this power will necessarily consume so much time that Nitrate Plant No. 2 could not wait for it, and it was decided to build a steam plant for use in the interim. The hydro-electric plant being therefore not essential for the operation of the nitrate plant, work on it was discontinued some months ago; but since the signing of the armistice with Germany it has been announced that this work has already been resumed.

The electric requirements of the various departments of the Nitrate Plant are estimated at 90,000 kw., 60,000 of which will be furnished by the large steam plant now under construction, and 30,000 will be generated by the Alabama Power Co. in a Government-owned extension to the Warrior steam power plant of that company situated in the Alabama coal fields at Gorgas on the Warrior River and transmitted 88 miles to the plant.

Steam-Power Plant Designed to Develop 90,000 Kilowatts

The steam power plant of Nitrate Plant No. 2 is located on the south bank of the Tennessee River about 3600 ft. north of the nearest plant building. It has been designed to develop, if necessary, the entire 90,000 kw. needed, by means of two units, Unit 1 of 60,000

kw. capacity, and Unit 2 of 30,000 kw., but in view of the resumption of work on the Tennessee River power development, it is not likely that the equipment for Unit 2 will ever be installed.

The boiler room (158 ft. 9 in. x 228 ft. 6 in.) will contain the 12 boilers of Unit 1, B. & W. Stirling type, water tube, each developing 1500 hp., and each equipped with B. & W. superheater and Diamond soot blower. The steam end of Unit 1 will be subdivided into three units of 20,000 kw. each. The turbine room is 170 ft. x 88 ft., equipped with Westinghouse turbines and generators—the latter A.C., 60 cycle, 3-phase, 12,200 volts. The turbines will be operated by steam at 275 lbs., 175 deg. F. superheat, and 28.5 in. of vacuum. The electrical accessory room (191 ft. x 35 ft.) will contain the necessary motors, batteries, rheostats, etc. The power house equipment includes also the necessary blowers for forced draft on the boilers, pumps, condensers, etc. Water for the condensers is taken from a coffer dam in the Tennessee River just north of the plant. Coal is brought into the plant in hopper-bottom cars on an overhead track, and is dumped into crushers, and the crushed coal is carried by screw-conveyors to the bunkers.

On Nov. 15 much work still remained to be done on the installation of the equipment of the power house, but it was then expected that the first 20,000 kw. subdivision of Unit 1 would be operating by Jan. 1.

Bus-Tunnel

The electric current at 12,000 v. will be transmitted from power-house to plant through a special bus-tunnel. This tunnel (built on the surface for the greater part of its length and underground for only about 200 ft.—at the point where railroad tracks will cross it) is 22 ft. 10 in. wide x 8 ft. high x 3600 ft. long. It is built of brick and concrete and has a gable roof of concrete

FIG. 1. ONE OF THE LIMEKILNS

slabs, covered with 3-ply felt and tar. Pent-houses at intervals of about 500 feet afford ventilation and means of access to the compartments of the tunnel. There are three compartments extending the entire length of the tunnel, separated by concrete walls. The two outside compartments are 5 ft. 8 in. wide inside and the middle compartment 8 ft. 10 in. wide. Attached to the concrete dividing walls are insulators which support the copper bus-bars. Each of the two dividing walls carries two bus-bar circuits—one circuit on each side of the wall. Thus there is one circuit in each of the two outside compartments of the tunnel, and two circuits in the middle compartment. Each circuit consists of 3 buses, supported one above the other on the wall and about one foot apart, and each bus is composed of two horizontally parallel copper bars, each ¼ in. thick x 4 in. wide. Expanded metal screens two feet away from the bus-bars will prevent persons who may be in the tunnel from coming in contact with the high voltage circuits, and will provide a safe passage for attendants or workman, 4 ft. 10 in. wide in the middle compartment, and 3 ft. 8 in. wide in the two outside compartments. Safety signals will also be provided to indicate whether the bars are alive or not. Provision has been made also for fire-doors by means of which one section of a compartment may be shut off from another.

At its upper end the tunnel terminates at the switch-house, where the electric current is diverted to the various departments requiring power.

The Carbide-Material Department

The purpose of the carbide-material department is to produce the quicklime and the crushed coke required by the carbide-furnace department, and its main functions are:

1. To pulverize the coal for the limekilns and coke driers.
2. To calcine (or burn) limestone in the limekilns, to form quicklime.
3. To crush and dry coke.

The limestone, quarried and crushed to sizes of from ½ in to 2 in. at the Government quarries at the Rockwood District near Russellville, Alabama (28 miles distant), is discharged from cars on a track at the north end of the limekiln building. The unloading of the cars is done either by dumping from drop-bottom cars or with the locomotive crane, as may be required. The crushed and sized limestone is carried by a conveyor belt to a bucket elevator, by means of which it is hoisted to an upper floor and distributed by means of a conveyor belt among seven concrete silos or bins, each of 6000 cu.ft. capacity.

A typical analysis of this limestone is:

Silica (SiO_2)	0.49 per cent
Alumina (Al_2O_3) and iron oxide (Fe_2O_3)	0.30 per cent
Calcium carbonate ($CaCO_3$)	98.23 per cent
Magnesium carbonate ($MgCO_3$)	0.97 per cent
Moisture and loss on heating to 175 deg. C.	0.07 per cent
Total	100.06

From the silos the limestone goes to a cradle feeding device, made by the Fuller Car-Wheel Manufacturing Co. of Catasaqua, Pa., which regulates the flow of limestone into the limekiln.

The limekilns are seven in number, each 8 ft. in diameter and 125 ft. long. Four of them were made by Reeves Bros., Alliance, Ohio, and the three others by the Allis-Chalmers Co. Fig. 1 is a photograph of one of these kilns. The kilns are nearly horizontal, having a pitch of 5 ft. in 125 ft. of length. They are steel shells lined with fire brick, and are rotated at the rate of about ½ r.p.m. by means of a beveled gear. The limestone is fed in at the upper end, and at the lower end the kilns are fired with powdered coal by an air blast. The temperature in the kiln is from 1400 to 2000 deg F. The product is quicklime and the reaction which takes place in the kiln may be expressed thus:

$$CaCO_3 = CaO + CO_2.$$

The process is continuous, but from three to four hours are required to complete the burning of the limestone. The capacity of the kilns is about 200 tons of

raw limestone per day each, equivalent to about 100 tons of burned lime. When the plant is fully tuned up, the combined capacity of the seven kilns will be from 1400 to 1600 tons of limestone per day.

From the limekilns (or limestone-burning kilns) the quicklime is discharged into seven horizontal cooling kilns, each 5 ft. in diameter and 50 ft. long, which revolve at the rate of about 3 r.p.m. The cooled quicklime is then conveyed to the raw materials building.

The coal-mill building (50 ft. x 125 ft.) situated alongside the kiln building, contains a coal bin, from which the coal is delivered to a crusher, thence to a steel silo, then to a coal drier. The latter is a rotary steel shell 42 ft. long x 3.5 ft. in diameter, fired externally by hand. The dried coal is carried up by elevator to steel silos from which it is fed to four Fuller 42-in. pulverizer mills. Thence it is carried up an elevator to a screw conveyor which takes it to small steel silos of which there is one opposite each limekiln. From these it is fed as needed, by means of an air blast, into the limekilns to effect the burning of the limestone.

At the coke-drier building, just east of the limekiln building, coke is dropped into hoppers underneath the track, and conveyed by belt conveyor to two crushers, where, after screening, the coarse is crushed to nut size and the crushed coke is then conveyed to two concrete silos, capacity 15,400 cu.ft. each, and thence fed down into four rotary driers, fired with coal. After drying, the coke is carried by belt conveyor to eight silos (capacity 6600 cu.ft.) in the raw-materials building, for use in the carbide-furnace department.

The raw-materials building (52 ft. 8 in. x 102 ft. 8 in.), located next to the limekiln building and south of it, is for the storage of the crushed coke and the quicklime, and designed to keep these materials as free from dampness as possible. From the bins in this building the materials are weighed in the desired proportions and mixed. The weighing apparatus beneath the two bins at the south end of the building consists of two 36-in. Schaffer poidometers, manufactured by the Schaffer Engineering and Equipment Co., of Tiffin, Ohio. These operate continuously, one for limestone and one for coke. They can be set to weigh the exact proportion desired, and both limestone and coke are delivered to the same conveying belt and carried to the carbide room.

Beneath the other bins there are three 8000-lb. scale hoppers, arranged for weighing either limestone or coke. The materials go from the scales to a conveying belt, to a bucket elevator, to another conveying belt, then in the carbide-furnace building are distributed among 24 steel silos, whence the charge, already mixed, can be dumped through chutes on to the charging floor of the carbide furnaces.

Carbide-Furnace Department

In the carbide-furnace building quicklime and dried crushed coke are heated to high temperature in an electric furnace, to form calcium carbide (CaC_2).

The size of the carbide-furnace building is 90 ft. x 1050 ft. and nine-tenths of this space is occupied by the carbide furnaces and their equipment. The building is the next building south of the raw-materials building, and its length extends from east to west, and its width from north to south. The carbide furnaces, of which there are twelve, are rectangular in shape, 12 ft. x 22 ft. x 6 ft. deep inside. They are merely steel boxes, open at the top and lined with firebrick.

At the east end of the carbide-furnace building there is a room 90 ft. x 100 ft. set apart for the assembly of the electrodes for the furnaces. The electrodes reach this room in the form of carbon blocks 16 in. square x 6 ft. 5 in. long. The assembly of electrodes consists in the following process: An area is planed at each side of one end of these carbon blocks, so that a metal head may make a good electrical contact. At the same end of each carbon block two holes are bored, and a copper electrode head is secured to it by special bolts. Then three of these blocks are fastened together as a unit and covered by wire netting and a protecting layer of heat-resisting cement (a mixture of asbestos and retort cement) which is baked on in an electric furnace. One complete electrode, assembled as described, weighs 7000 lb. Pipe connections are made to the electrode heads, which are provided with a water-cooled system, for cooling the electrodes while in service.

Three of the complete assembled electrodes are suspended from suspending arms over the top of the furnace. The depth of immersion of the electrodes in the molten bath is controlled automatically on the electric switchboard. The bus-bars carrying current to the electrodes are $\frac{5}{16}$ in. thick x 8 in. wide, and there are 16 bars to each electrode. The voltage for the carbide furnaces is 130 v. stepped down from 12,000 v. by G. E. transformers. There is one bank of transformers for each furnace, the capacity of each bank being 8325 kw. The current used at present is 15,000 amp., but when operating normally the current will be 20,000 amp. The normal capacity per furnace is 50 tons per day of 24 hours. The temperature attained in the furnace is 3000 deg. C. During the reaction the electrode is consumed at the rate of 70 lb. of carbon per ton of carbide manufactured. The reaction may be expressed thus:

$$CaO + 3C = CaC_2 + CO$$

The carbon monoxide burns at the top of the furnace and escapes as carbon dioxide.

On the bottom of the furnace is placed one layer of graphite electrodes, 16 in. square x 48 in. long. On top of this layer of electrodes is placed a layer of tar and gravel. In starting a furnace, a layer of crushed coke is thrown in on the bottom. The charge is put in on top of the layer of coke and the current is turned on. The charge consists of a mixture of quicklime and dried crushed coke, in the proportions of 1000 lb. of the former to 600 to 620 lb. of the latter. This mixture is made up in the raw materials building and conveyed to the charging floor of the carbide furnaces as previously described, and is shoveled into the furnace until it is full to the top. The first tap is made six hours after starting, and thereafter the furnace is tapped every 45 minutes, the furnace being kept full to the top all the time by men on the charge floor, shoveling in the mixture as required.

The furnace is tapped by burning out the tapping hole with a portable electrode, whereupon the molten carbide flows out into "chill cars" of one-half ton capacity each. After tapping, the tapping hole is stopped by throwing a few shovelfuls of powdered carbide at

the outlet. The outflowing mass soon solidifies and the flow is stopped. The chill cars containing the hot carbide are hauled by electric locomotives operated by storage batteries to the carbide-cooling building, which is a part of the next department.

Carbide-Mill Department

The carbide mill department is responsible for cooling, crushing and pulverizing of the carbide for use in the lime-nitrogen department. The carbide-cooling building (950 ft. long x 50 ft. wide) is located south of the carbide-furnace building and parallel to it, and is connected to it by six passageways each 50 ft. x 50 ft. As contact with water will produce acetylene, care must be taken in cooling to protect the carbide from rain and snow. The buckets containing the carbide pigs are picked off the cars by a traveling crane, and set aside to cool. During the process of cooling, considerable shrinkage takes place; when sufficiently cooled, the pigs or blocks of carbide are dumped out of the buckets on to the crusher platform.

The following is a typical analysis of the manufactured carbide:

CaC_2	82.30 per cent	Ca_3P_2	0.07 per cent
C	1.20 per cent	CaS	0.13 per cent
CaO	14.72 per cent	FeSi	0.72 per cent
CaSi	0.06 per cent	Undetermined.	0.80 per cent

The carbide-crusher building (120 ft. x 150 ft.) contains three 36-in. x 42-in. Buchanan crushers, which crush the carbide to about 1¼-in. size. After crushing, the material goes by elevator to a bin which supplies the Hardinge mills, of which there are three. These grind the carbide so fine that 80 per cent of it will pass through a 40-mesh screen, and the balance through a 10-mesh screen. From the Hardinge mills the powdered carbide goes to three Smidth tube mills, which pulverize the carbide still further, so that 85 per cent will pass through a 200-mesh screen, and the product is known as milled carbide.

While going through the process of milling, the carbide must be protected from the moisture of the air, which, acting on the finely divided carbide, might react with it, forming acetylene, a gas of an explosive or inflammable nature when mixed with air. The grinding and milling of the carbide are therefore done in an atmosphere of nitrogen, this inert gas being piped to the carbide-crusher building from the liquid-air building, for use in the grinding and pulverizing mills.

The milled carbide is conveyed to eight steel bins or storage silos in the lime-nitrogen building. The pulverized carbide constitutes only one of the two important raw materials for the manufacture of lime nitrogen; the other one is the nitrogen.

Nitrogen Department

The nitrogen is obtained from air in the liquid-air building. The process, described briefly, consists in the compressing and cooling of air until it becomes liquid, then in the fractional distillation of the liquid air to separate the nitrogen from the oxygen in much the same manner as alcohol is separated from water, advantage being taken of the different temperatures at which the two gases change from the liquid state to the gaseous.

The liquid-air building (100 ft. wide x 575 ft. long) is located ¼ mile to the east of the lime-nitrogen building. The object of this isolation is to have the air intakes and the equipment of this department away from the contaminating gases of the other departments of the plant.

The air intakes for the liquid-air process consist of two 36-in. pipes, which extend, one north and the other south, for 1600 ft. in either direction, from a point opposite the center of the building, on the east side, for the sake of getting a supply of pure air. By means of Root cycloidal blowers the air is drawn through the intakes and then is forced through eight sets of scrubbing towers (two towers to a set). These towers, 8 ft. in diameter and 30 ft. high, are packed with 6-in. spiral rings. The towers are fed with a solution of caustic soda (17 deg. Bé.), a fresh solution to each tower. The object of the scrubbing of the air is to remove impurities, chiefly the 0.04 per cent of carbon dioxide, which, if not removed, would give trouble in the subsequent operations by freezing. The caustic liquor discharged from the scrubbers goes to the ammonia-gas department, where the carbonate is removed, and the caustic solution made up to strength and returned to the liquid-air department. From the second towers the air goes to the main header, and is thence supplied to the compressors.

The Liquid-Air Plant

The engineer who designed the liquid-air plant is Herman Van Fleet of Philadelphia. Fundamentally the process used is the Claude process. There are 15 twin-duplex compressor units, furnishing air at 600 lb. pressure to 30 nitrogen columns. Seven of these compressors were furnished by the Ingersoll-Rand Co. and eight by the Norwalk Iron Works. The compression is done in three stages: 30 lb., 140 lb. and 600 lb. Of the 30 nitrogen columns, 24 will be operating normally—the six others being spares. The nitrogen columns were made by the Ansonia Brass and Copper Co., Cincinnati, Ohio, and the rights to their use are controlled by the Air Reduction Co. The columns, oval in shape, are about 4½ ft. in diameter and 24 ft. high. The rectifier in the nitrogen column consists of a series of superposed horizontal trays, each about 1½ in. deep, on which rests a body of liquid through which the rising gas must bubble.

The compressed air from the Norwalk or Ingersoll-Rand compressors is allowed to expand from 600 lb. to 50 lb. In expanding, the air operates a small engine, generating thereby about 4 to 5 hp., this power going to waste. The air at 50 lb. pressure enters the rectifier, and at this stage is below the critical temperature of air (—140 deg. C.). A small part (about one-tenth) of the air at 600 lb. is admitted to the rectifier at that pressure, and the increased pressure on the cold air at 50 lb. pressure liquefies the air. The liquid air then begins to distil. Oxygen liquefies at —182 deg. C. and nitrogen at —195 deg. C. Oxygen, therefore, tends to remain liquid, and the nitrogen tends to go over into the gaseous state. Therefore, a liquid rich in oxygen (45 to 50 per cent O) is found at the bottom of the rectifier, and the gas in the rectifier gradually becomes richer in nitrogen as it approaches the top. At the top of the rectifier the gas is sprayed with liquid nitrogen, and gaseous nitrogen, 99.9 per cent pure, escapes.

Tests of the percentage of oxygen in the gas mixture inside the rectifier are made from time to time, for regulation of the apparatus.

The nitrogen is passed through two pipe heat-exchangers, to recover the cold, then goes to the nitrogen header, then through a 30-in. main to the lime-nitrogen building. The nitrogen escapes from the rectifier under a pressure of 10 in. of water and goes to the lime-nitrogen building under a pressure of 4 in. of water. Each nitrogen column produces nitrogen at the rate of 500 cu.m. (1765 cu.ft.) per hour. The oxygen is passed through the heat-exchanger and is then allowed to escape into the atmosphere of the building.

The illustration (Fig. 2) is a photograph of the interior of the liquid-air building. In the middle foreground is one of the nitrogen columns with its engine and heat-exchangers and other nitrogen columns can be seen farther to the right. At the left, in the background, is one of the duplex-compressor units.

The compressors for the service air for the entire nitrate plant have for convenience been installed in the liquid-air building, at the north end. For furnishing service air there are five Sullivan two-stage angle compound air compressors, furnishing air at 100 lb. The air goes to the compressors through a 28-in. intake, and is delivered to the plant through two 10-in. mains, which are so connected that one can be shut down for repairs if necessary without interfering with the air service to the plant. These five compressors have a combined capacity of 10,000 cu.ft. of free air per minute.

Lime-Nitrogen Department

The lime-nitrogen building is 250 ft. wide and 520 ft. long, and is located south of the carbide-mill building. In this building the milled carbide and the nitrogen are brought together to form lime nitrogen, commercially known as crude cyanamide.

There are sixteen rows of lime-nitrogen ovens and 96 ovens in a row—1536 ovens in all. Eight rows of the ovens are located on the west side of the building, occupying 100 ft. of the width, and the other eight rows on the east side likewise occupy a space 100 ft. wide, leaving a space 50 ft. wide in the center, extending from north to south, which is used for the manufacture of the paper containers and tubes employed in charging the ovens.

The ovens are 4 ft. 4 in. outside diameter x 2 ft. 10 in. inside diameter x 5 ft. 4 in. deep. They consist of a steel shell with a 9-in. lining of Evans & Howard fire-brick. To charge the oven a cylindrical paper container 2 ft. 6 in. in diameter, with a vertical paper tube 3 in. in diameter in the center, is inserted in the cold oven, and the charge of about 1600 lb. of pulverized carbide is put in. There will be an annular space about 2 in. wide between the paper container and the brick lining of the oven. The carbon electrode, a $\frac{5}{8}$-in. pencil 6 ft. 6 in. long, is inserted inside the paper tube. Two covers are put on, the outer cover being luted with sand.

For bringing the nitrogen to the ovens there is an 8-in. spiral riveted pipe between each pair of parallel rows of ovens, and from this two $1\frac{1}{2}$-in. pipes convey the nitrogen to the oven—one to the bottom, at the center, and the other at the side, 6 in. above the bottom—each provided with a valve. The nitrogen reaches the oven under a pressure equal to 3 to 4 in. of water.

When everything is ready, the electric current (single phase) is turned on at 100 volts and 200 to 250 amp. for 20 minutes, then it is reduced to 50 volts and 100 to 115 amp. for 12 hours. Then, as the reaction is exothermic, the current is shut off and the reaction allowed to continue 28 hours longer. The temperature

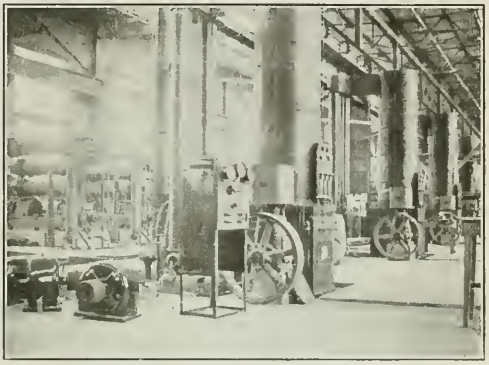

FIG. 2. NITROGEN COLUMNS, LIQUID-AIR BUILDING

attained in the oven is about 2000 deg. F. The material is not melted, but sinters together to form a solid cake.

In the oven the nitrogen is absorbed by the carbide, and carbon is set free, the chemical equation being:

$$CaC_2 + N_2 = CaCN_2 + C$$

A typical analysis of the lime nitrogen follows:

$CaCN_2$	63 per cent	SiO_2	3 per cent
CaC_2	2 per cent	MgO	2 per cent
CaO	13 per cent	Fe_2O_3 and Al_2O_3	2 per cent
CaS	1 per cent	Miscellaneous	3 per cent
C	11 per cent		

For removing the cakes or blocks of lime nitrogen, and otherwise serving the ovens, an industrial track has been provided in the building with cars drawn by gasoline locomotives. The finished cyanamide is taken to the lime-nitrogen-mill department for cooling.

Lime-Nitrogen-Mill Department

The lime-nitrogen-mill department has three functions to perform:

1. To cool the cyanamide pigs.
2. To crush and mill the cyanamide.
3. To remove from the cyanamide some of the undecomposed carbide by a hydration process.

The lime-nitrogen-cooling building (50 ft. x 350 ft.) is at the south end of the lime-nitrogen-oven building. It is served by two 20-ton Whiting cranes. The cooling of the cyanamide blocks does not require as much care as was the case with the carbide pigs, as the material does not now combine readily with water to form acetylene gas. After cooling, the cyanamide blocks are crushed and pulverized.

The cyanamide-mill building is an exact duplicate of the carbide-mill building. The cyanamide is pulverized so that 95 per cent will pass through a 200-mesh screen.

All grinding and pulverizing is done in an atmosphere of nitrogen. The milled cyanamide is taken to nine large concrete silos in the lime-nitrogen-silo building (56 ft. sq. x 76 ft. high), south of the mill building. From these silos the material goes to the hydrating building (size 50 ft. x 80 ft.). Here the milled cyanamide is conveyed by screw conveyors to an elevator and thence to a hopper-feeding device, which feeds so many pounds per hour to the hydration troughs. There are three of these, 36 ft. long x 3 ft. in diameter, open top, and each containing a horizontal revolving shaft with many projecting arms 20 in. long. Water, in amount proportional to the free carbide in the cyanamide as shown by chemical analysis, is sprayed in at the feeding end of the trough. The material becomes damp and is conveyed by the revolving agitator to the other end, by which time the material must be perfectly dry. The agitator, revolving at the rate of 50 r.p.m., conveys the material along the trough at the rate of about 50 ft. a minute. The acetylene liberated in the hydration building goes to waste. The reaction in the hydration trough is:

$$CaO + CaC_2 + 3H_2O = 2Ca(OH)_2 + C_2H_2$$

From the hydrating troughs the dry cyanamide is discharged into a screw conveyor, and carried through an overhead tunnel to the autoclave building, 300 ft. away to the south, there to be converted into ammonia.

Ammonia Gas Department

The principal building of this department is the autoclave building, but auxiliary apparatus is contained in the process boiler house and in the filter building, while the dephlegmators and steam condensers are out-of-doors, between the autoclave building and the process boiler house.

The latter must not be confused with the main power house, which was described at the beginning of this article. The process boiler house is to furnish steam for the autoclaves, also for heating the various plant buildings. It is located about 100 ft. to the east of the autoclave building. The equipment consists of four 825-hp. B. & W. Stirling type boilers, with the necessary feed-water pump and water-measuring apparatus. The boilers are fired by Westinghouse stokers from overhead bunkers. Coal is delivered to the boiler house on a track north of the building, and is dumped into a hopper beneath the track, and conveyed to a crusher, then elevated to the bunkers. The operating pressure of these boilers is 150 lb.

The autoclave building (81 ft. x 252 ft.) contains the autoclaves for the manufacture of ammonia from cyanamide. The autoclaves are cylindrical steel tanks, 8 ft. in diameter and 20 ft. high, each provided with a vertical agitator, which revolves at the rate of 12 r.p.m. throughout the continuance of the reaction. There are 56 autoclaves in all, made of 1¼-in. steel by M. W. Kellogg, New York.

The milled cyanamide, arriving at the autoclave building, is hoisted by a bucket elevator to an upper floor, and dumped into a steel silo. From this it is fed into 14 hopper bins, and these discharge into weigh bins. Each weigh bin feeds into a 5-in. screw conveyor, which in turn supplies a 12-in. screw, delivering to 4 autoclaves.

Before charging any cyanamide into the autoclave, a 2 per cent solution of caustic soda is run in to a depth of 9 ft. Then about 300 lb. of soda ash is added. Since the cyanamide carries about 13 per cent of free lime, the latter reacts with the soda ash to form some additional caustic soda, thus making the solution equivalent to 3 per cent in strength. After the addition of the soda ash the charge of cyanamide, 8000 lb., is admitted. The cyanamide, even after leaving the hydration building, still contains about 2 per cent of undecomposed calcium carbide, so that the first reaction in the autoclave, when the lime nitrogen comes in contact with the caustic soda solution, results in the generation of acetylene. All valves on the autoclave are closed except one, and through that one the acetylene is allowed to escape through an exhaust fan. After all of the acetylene has passed off, the outlet pipe is shut and clamped tightly. Then steam is admitted at a pressure of 150 lb. for 20 minutes. Ammonia gas begins to form in the autoclave. The reaction is exothermic. When the pressure in the autoclave rises to 250 lb., the ammonia escape valve is opened cautiously, but the pressure is maintained constant for 3 hours. By this time the pressure begins to fall off, and the ammonia is allowed to escape. The ammonia valve is closed again and steam is admitted a second time for 20 minutes. The reaction continues this time at 200 lb. pressure for an hour and a half. The chemical reaction in the autoclave is expressed:

$$CaCN_2 + 3H_2O = CaCO_3 + 2NH_3$$

This operation must be carefully controlled to prevent the pressure from rising too high, which would result in loss of valuable ammonia through the safety valves.

The gas escaping from the autoclaves (about 25 per cent ammonia and 75 per cent steam) goes to a header at the north end of the building, then to seven mud drums, then to seven dephlegmators, or ammonia columns. These are about 10 ft. in diameter and 25 ft. high, and each contains 16 horizontal plates. The gas enters at the bottom, and rising through 4-in. holes in the plates, covered with bell-shaped caps, bubbles through ammonia liquor standing on the plates or shelves. The gas then goes into 14 condensers (seven sets with two connected in series to each set). The condensers contain vertical tubes through which water circulates, and here the steam is condensed. The ammonia gas then goes to a 28-in. pipe, which is tapped by two 20-in. mains, one of which conveys 55 per cent of the ammonia to two 60,000-cu.ft. receivers, to supply the catalyzer plant, while the other carries 45 per cent of the gas to the neutralizer building. The capacity of the plant is 1000 tons of ammonia gas per week.

The Filter Room

A quantity of sludge, consisting chiefly of carbonate of lime, caustic soda, free carbon, etc., remains in the autoclave, and must be removed before recharging. An 8-in. outlet at the bottom of the autoclave permits the sludge to be blown out with steam or air. It flows by gravity to the filter room (151 ft. x 160 ft.) adjoining the autoclave building, where it is treated for the recovery of the caustic soda. In the filter room there are two sets of Oliver rotary filters, ten filters to a set. Each of the four sludge troughs feeds into five

filters which operate under a suction of 20 in. of mercury, produced by three vacuum pumps. The caustic soda solution, now reduced in strength to only 2 per cent, is sucked out, and the cake is scraped off into a conveyor and discharged to the sewer.

The filtrate goes through two tanks and is pumped by seven 650-gal. Gould centrifugal pumps to eight filtrate storage tanks containing cooling coils. From these it is drawn to seven filtrate measuring tanks, from which it is returned to the autoclave. It is in this filter room that the caustic soda solution coming from the scrubbing towers in the liquid-air building is brought up to strength. It is then returned to the nitrogen department.

Nitric-Acid Department

The nitric-acid department comprises the catalyzer buildings, the oxidation towers and coolers, and the absorption towers for making nitric acid.

There are six catalyzer buildings, each 50 ft. x 210 ft., and each consisting of two units. On the west side of each catalyzer building there is a meter room. Under the meter room is a 5½-ft. air duct fed by blowers located in the first meter room. Ammonia gas is drawn

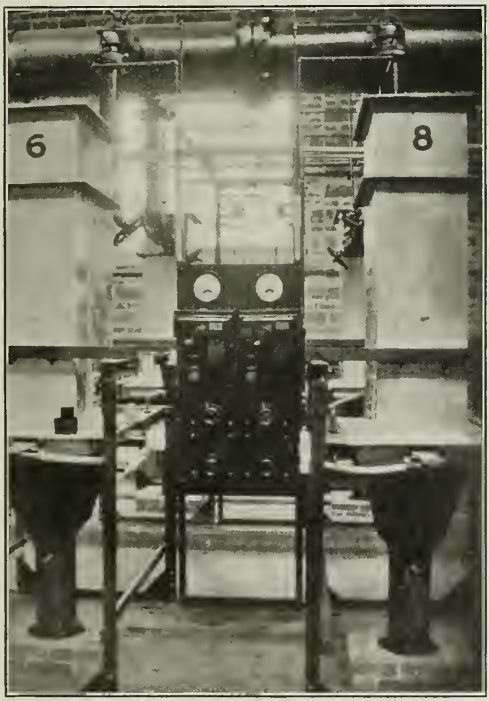

FIG. 3. CATALYZERS FOR OXIDIZING AMMONIA GAS

from the receiving tanks into which it was delivered from the ammonia-gas department, and by means of meters it is mixed with air in the proportion of 1:9 or 1:10. The mixture is passed into 12 steel mixing tanks (8 ft. in diameter x 30 ft. high) which are filled with 6-in. spiral rings. From the mixers the gas goes to the catalyzers.

In each catalyzer building there are four rows of catalyzers, 29 to a row, or 696 catalyzers in all. The photograph (Fig. 3) shows two catalyzers, with switchboard between, while Fig. 4 shows a row of catalyzers, with ammonia-feed pipe overhead and gas-discharge pipes leading out of the bottoms into a common flue. The catalyzers are spaced 5 ft. apart. The ammonia gas enters at the top through an iron pipe flanged to the aluminium casing, which is a rectangular box, 14 in. x 28 in. x 5 ft. high. At the base of the aluminium box there is a sheet of platinum gauze suspended in horizontal position. This gauze is made of $\frac{3}{1000}$ in. platinum wire, contains 80 meshes to the inch, and each sheet weighs 4.6 troy ounces. Each catalyzer has an 8-kw. transformer, and operates at 21 volts, stepped down from 460 volts, and 375 amperes. The platinum gauze is heated by the electric current to 750 deg. C. The ammonia gas, passing through the incandescent platinum gauze (which can be plainly seen through a small window in one side of the aluminium box) is converted into nitrogen oxides, and the converted gas escapes through a cast-iron pipe at the bottom of the catalyzer to a flue or tunnel made of concrete lined with chemical brick laid in acid-proof cement. These flues or tunnels convey the oxides of nitrogen to the oxidation towers and coolers.

The building for these towers and coolers is 100 ft. wide x 600 ft. long. There are 24 high-temperature coolers which are merely horizontal boilers supplied with steam at 25 lb. pressure. In these boilers the gas, passing through the boiler tubes, is cooled from 600 deg. to 200 deg. C. It then goes to 12 low-temperature coolers, through aluminium pipes 30 in. in diameter.

The low-temperature coolers consist of a rectangular chamber, divided into five compartments by four walls which do not reach entirely across the width of the chamber. The gas is thus caused to take a zigzag course through the chamber. Suspended from the top of the chamber are a large number of 5-in. tubes 7 ft. long—140 tubes to each of the five compartments. In two of the compartments the tubes are made of chemical stoneware, and in the three others of duriron, and each tube is provided with an outlet lip at the top. Inside each tube there is an inner tube, down which water flows. Escaping at the bottom of the inner tube, the water rises in the outer tube and escapes at the lip.

The gas is thus cooled to 30 deg. C. In these coolers nitric acid begins to form, and part of the nitric oxide becomes oxidized to nitrogen peroxide. The nitric acid formed is drained into No. 3 well of the absorption tower system. The gas, now a mixture of NO and NO_2, goes to the oxidation towers.

The Oxidation Tower

There are 12 oxidation towers, 15 ft. square, made of chemical brick. Each tower is divided by two walls into four equal compartments. The gas passes up one compartment, over the top of the dividing wall, down the next, through a hole at the bottom of the next wall, up the next compartment, over the wall, and down the last compartment. The gas is now practically all N_2O_4, and in this state passes on to the absorption towers.

The absorption-tower building (100 ft. wide x 600 ft. long) is located next to the oxidation towers, and to the

southeast of them. In this building there are twelve units of absorption towers, two towers to a unit connected in series. The structural steel for the towers is heavily coated with pitch, to protect it against corrosion. The towers, built of acid-proof brick laid in acid-proof cement, are 35 ft. square x 60 ft. high. Each tower is divided by interior brick walls into four compartments, as in the oxidation towers. The first tower of each unit is packed half way up with 6-in. spiral rings, and the upper half is packed with 3-in. spiral rings. The second tower of each unit is packed entirely with spiral

FIG. 4. VIEW IN CATALYZER BUILDING

rings of the 3-in. size. The gas from the oxidation towers passes into the first absorption tower of each unit, then into the second. In passing through the four compartments of each tower the gas pursues a course similar to that taken in the four compartments of the oxidation towers—up one compartment, down the next, and so on. Water is sprayed into the top of that compartment of the second towers of each unit last reached by the gas. From there on, the liquid pursues a course through the compartments of the two towers of each unit opposite to that taken by the gas, the liquid discharged from each compartment being used to feed to the top of the next forward compartment in the series. Thereby the liquid becomes progressively stronger in nitric acid as it passes from one compartment to another, until when it reaches the front compartment it has a strength of 50 per cent. The reactions in the absorption tower are expressed thus:

$$2NO_2 + H_2O = HNO_3 + HNO_2$$
$$HNO_2 + NO_2 = HNO_3 + NO$$
$$2NO + O_2 = 2NO_2$$

The pumping of the liquid is done by means of air lifts—a one-stage lift for each compartment of the 24 towers (96 in all) and 24 spares. To accommodate these lifts 120 wells, 12 in. in diameter and 100 ft. deep, were bored. The air lifts are made of 3-in. aluminium pipe, the lengths flanged together with duriron flanges. Air at 100 lb. is supplied to the air lift through a 1-in. pipe. The acid in that part of the air lift inside the well is cooled by water, constantly circulating into and out of the well. An electric signal system, connected to a signal lamp, will be provided for each well, for indicating any leakage of acid into the cooling water. On account of the low conductivity of pure water, the lamp will remain dark as long as there is no acid escaping, but the moment the least leakage occurs the acidulated water becomes a good conductor and the signal lamp becomes luminous.

The acid is pumped to the top of each compartment to a separator, where the air escapes. Then the acid goes to a distributor box, then to sprayers on the top of the tower.

Between the first and second towers of each unit there is an aluminium exhaust fan drawing the gas from the first tower and forcing it through the second. After the second tower of each unit there is another aluminium fan which discharges the residual gas into the atmosphere. The acid outlets for the towers are of 4-in. duriron pipe, flanged to the 3-in. aluminium air lift.

The final product of the towers is delivered to 12 aluminium weighing tanks (about 10 ft. in diameter and 12 ft. high) on scales, and is then discharged into 12 storage tanks, 25 ft. in diameter and 10 or 12 ft. high, made of concrete and lined with acid-proof brick. From the storage tanks the acid is drawn off by a 3-in. aluminium siphon to a 4-in. duriron header which conveys the acid to the next department.

The Nitrate Department

There are two branches of the nitrate department: (1) The neutralizing building, where the nitric acid is neutralized with ammonia gas, and (2) the crystallizing buildings.

In the neutralizing building (93 ft. wide x 150 ft. long) there are four absorbing towers with two mixing tanks, four condensers, four neutralizing tanks, four settling tanks, one receiving tank and three filter presses. There are also eight settling tanks located outside the building.

The nitric acid comes from the storage tank to the mixing tank, then by means of an air lift is elevated to the top of the absorbing towers. The latter are 7 ft. square x 20 ft. high, packed with 3-in. spiral rings. The unabsorbed ammonia gas from the neutralizing tank (see below) passes up these towers. From the bottom of the tower the liquid goes to the mixing tank; from this tank it is pumped to a distributing pot on top of the tower and from that it is drawn off to the neutralizing tank. The liquid still has an excess of nitric acid.

The Neutralizing Tank

In the neutralizing tank there are four 10-in. inlets for ammonia gas at the top. There is always about 3 ft. of liquid in the tank, so that the ends of the ammonia pipes, projecting through the top, are immersed in the liquid and the ammonia gas is forced to bubble through. The nitric acid is thus neutralized and ammonium nitrate, in solution, is formed. The reaction is:

$$HNO_3 + NH_3 = NH_4NO_3$$

The unabsorbed ammonia gas passes through a condenser which is like the low-temperature gas cooler for the gases leaving the catalyzers, only much smaller, then passes through the absorbing tower, where it meets nitric acid as previously described.

The ammonium nitrate solution goes from the neutralizer to storage tanks, then to the settling tanks. From time to time the sediment is taken out and put through the Sperry filter press. The filtrate goes to the filtrate tank and is re-treated. The final settling is done in eight ammonium nitrate tanks, where the liquor is stored for the next process—crystallization.

There are five ammonium nitrate or crystallizer buildings, each 60 ft. wide x 120 ft. long. They are all located 500 ft. apart and 500 ft. from any other building, as a precaution against explosion or fire. Being the scene of the last operation in the process, they are located at the southern extremity of the nitrate-plant site. Each building is supplied by a 6-in. pipe for ammonium nitrate solution, a 6-in. steam pipe, a 2½-in. compressed-air pipe, and a 2½-in. pipe for ammonia gas for completing neutralization in case the liquor should come up slightly acid.

Evaporating Pans

Each building has a storage tank for nitrate liquor (10 ft. in diameter x 12 ft. high) and ten evaporating pans, coated on the inside with a blue-enameled lining. These pans are 11 ft. long x 6½ ft. wide x 2¾ ft. deep. The pure nitrate solution is pumped to the crystallizer building, and from the storage tank there is drawn into the evaporating pans. The evaporation is accomplished by means of steam pipes. There are in each evaporating pan six 3-in. aluminium steam pipes, extending the full length of the pan and back again. Each evaporating pan is also equipped with three ½-in. air pipes, also of aluminium, which are used for agitating the liquid by means of compressed air, to facilitate evaporation. Over each pan there is a hood and flue for carrying away the fumes. Each pan is set up on six pedestals 2½ ft. high, so that the top edge of the pan is nearly 5 ft. from the floor, with ample air space underneath.

Each pan drains into two open-top crystallizing kettles, each 6 ft. in diameter x 2 ft. 2 in. deep, jacketed, and piped in such a way that they can be either steam-heated or water-cooled. They are also provided with an agitator, which revolves at the rate of 17 r.p.m.

The nitrate liquor is evaporated in the pan to the crystallizing point. It is then withdrawn at a temperature of 145 deg. C. from the pan to the kettle, where at first it is heated by means of steam in the jacket, so as to cool it gradually; then the steam is shut off and cooling water is admitted to the jacket while the agitator continues to revolve, and the ammonium nitrate crystallizes out in the kettle. A gate on the side of the kettle is opened and the agitator sweeps out the crystals on to a clean floor.

In appearance the ammonium nitrate is much like coarse-grained common salt. It is shoveled down through a hole to a lower floor, and is packed for shipment. The capacity of the five buildings is to be 300 tons of ammonium nitrate per day.

Water System

All water used in the chemical processes of this plant, as well as water for domestic and fire protection purposes, will be pumped from the main power house. For this purpose four 18-in. Allis-Chalmers centrifugal pumps, each with a capacity of 9730 gal. per minute, under a head of 200 ft., will be used. The water discharged from these pumps will be carried through two 36-in. cast-iron pipe lines running parallel from the power-house to the summit of the bluff to the south, about 3500 ft. away, thence through a 72-in. reinforced-concrete duct by gravity about 600 ft., into a settling and storage reservoir. This reservoir has a capacity of 60,000,000 gal., and has a settling area, when full, of 900,000 sq.ft. The water for the process may be taken direct from the reservoir through 36-in. reinforced-concrete pipe into cast-iron mains, or it may pass through the pumping station if more pressure is required. This station contains four 18-in., 9730-g.p.m. centrifugal pumps driven by 500-hp. motors, delivering into the process mains. The water for domestic purposes will be treated and filtered at the filtering plant just below the level of the reservoir and will discharge into the pumping station, where it will be handled by two 4-in. centrifugal pumps of 300-g.p.m. capacity each, driven by 25-hp. motors, and two 5-in. centrifugal pumps of 750-g.p.m. capacity, driven by 50-hp. motors. In this pumping station there will also be two 8-in. centrifugal fire pumps of 1500-g.p.m. capacity, each driven by a 100-hp. motor.

Long as the above description may seem, it does not by any means do justice to the plant. To cover adequately all the details of the process a volume could be written on each of the ten departments. This brief survey merely calls attention to the more important parts of the equipment and touches on the vital features of the process. It is difficult for any one who has not seen the plant to realize its magnitude—to grasp that there is at Muscle Shoals a huge plant of ten departments, any one constituting a large plant in itself, and the ten combined giving employment, when operating at full capacity, to between 3000 and 4000 men. The construction up to Nov. 15, 1918, and then incomplete, was said to have cost $60,000,000.

Built in Less Than a Year

The principal contractors for the plant have been: (1) The J. G. White Engineering Corporation, New York, in charge of power-house installation complete, bus-tunnel line and process-pipe lines (36 in.) for the water reservoir; (2) Westinghouse, Church, Kerr & Co., New York, in charge of erection of plant buildings, etc.; and (3) Chemical Construction Co., responsible for the construction and installation of much of the chemical equipment, such as towers and their accessories, coolers, gas flues, tanks, etc.

On Nov. 25, 1918, individual units were operating in every building as far as the lime-nitrogen-mill building, the product having reached that point on its way through the process. Units in all the other departments were being tuned up and dried out. The power in use, only 5000 kw., was being delivered to the plant by the Alabama Power Co. It was expected that by the latter part of December the plant would be operating at the rate of 30,000 kw. (33⅓ per cent capacity); by Jan. 1, 1919, at the rate of 50,000 kw. (45 per cent capacity); and by Feb. 1, at the rate of 90,000 kw., or full capacity. If this schedule is adhered to, the plant will be in full operation in less than one year from the date of first breaking ground.

Exhaust Steam at High Back Pressures

A System of Charts Based on Thermodynamical Formulae and Data with Reference to Boiler Pressures and Cutoffs—Description of an Eight-Ton Dye Plant Operation Using Steam Jacketed Evaporating Pans, Vacuum Driers, Kettles and Chambers

BY CROSBY FIELD

STEAM as exhausted from an engine contains approximately 85 per cent of the amount of heat contained in the steam supplied to the engine. This fact has long been recognized and attempts have been made to utilize exhaust steam for many industrial purposes, but due to the high temperatures used in the dyestuff and other similar chemical industries full value of the exhaust steam has not been attained therein.

The object of this paper is to provide a set of charts from which the plant engineer can very rapidly determine just what back pressure would be the economical one for him to use provided the chemical processes involved do not require a higher temperature than that provided by this back pressure. A method is also suggested whereby the plant engineer may use some of this exhaust steam when the process requires a temperature too great for exhaust steam at the economical pressure.

The pressures to which exhaust steam can economically be carried are very much higher than is usually thought. For several years past the writer has very successfully used back pressure at 50 lb. per sq.in. gage and under some conditions has used 80 lb. per sq.in. gage. This is accomplished with absolutely no deleterious effect upon the machinery.

It is not to be assumed that the writer believes that high back pressures are universal panacea, but he does believe that they should be used much more than they have been in the past.

EXPLANATION OF CHARTS

Instead of dealing with these subjects theoretically and including a large number of interesting formulæ, which the plant engineer will probably never have the time to investigate, the accompanying charts used by the writer in his practice are given, and in addition examples of their use. In referring to these it must be remembered that:

They are all based on the theoretical expansion curve of steam, i. e.,

$$P_m = p_i \frac{1 + \text{hyp. log. } R}{R}$$

or $P_m = P_t\ (1 + \text{hyp. log. } R)$

wherein

P_m = absolute mean pressure

p_i = absolute initial pressure considered uniform up to cutoff

P_t = the terminal pressure

R = ratio of expansion.

They are not offered as accurate scientific work, but merely as being charts found of value to the writer and of sufficient accuracy to warrant their continued use. It is believed that these approximate all of the commercial cutoffs. It must be remembered that they are purely theoretical curves and give an approximation only of actual conditions. It is believed, however, that in most cases these curves will solve the problem to an accuracy of from 5 to 10 per cent, which is sufficiently close for the plant engineer, as the inaccuracy due to the differences of operation at various times will usually more than offset this.

On both the sets of curves from Figs. 2 to 12 inclusive, an additional scale has been run giving the theoretical increase in the weight of steam used for the same power due to the increased back pressure, so that all needed quantities can be read off of the chart at once. Fig. 13 is necessary when it is desired to solve complicated cases which cannot be readily solved by a single reading of the previous charts.

EXAMPLES—USING CHARTS

For illustration, assume a color plant producing 500,000 lb. total of several colors per month, containing the following chemical apparatus:

20 Evaporating pans,
10 Vacuum driers,
20 Jacketed cooking kettles,
5 Air blast dry rooms,
Large number of tube containing materials boiled by injection of live steam through pipes, etc.

Upon closer investigation, the following summary presents itself:

SAMPLE SUMMARY SHEET OF STEAM CONSUMPTION IN DYESTUFF PLANT

Item	Apparatus	Number	Temp. of Product Deg. F.	At Present Supplied by	Remarks
1	Evaporating pans	15	214	Boiler steam through reduction valve to 35 lb.	This pressure is as high as can be used satisfactorily in order to prevent boiling over.
2	Evaporating pans	5	214	Boiler steam through reduction valve to 5 lb.	
3	Vacuum driers	5	?	Boiler steam through reduction valve to 3 lb.	This pressure cannot be raised due to danger of burning product
4	Vacuum driers	5	?	Boiler steam through reduction valve to 40 lb.	
5	Cooking kettles	10	230	Boiler steam through reduction valve to 80 lb.	
6	Cooking kettles	5	240	Boiler pressure	
7	Cooking kettles	5	260	70 lb.	
8	Air blast dry room	5	100 to 180	Boiler pressure	

The above apparatus consumes an average of 50,000 lb. of steam per hour and 700 kw.-hrs. per hour. Assuming this latter equivalent to 29,000 lb. (see below), the total steam required is 79,000 lb. per hour.

Item 1 can be operated on a pressure of 35 lb. or over, item 2 on a pressure of 5 lb. or over, item 3 on a pressure of 3 lb. or over, item 4 on a pressure of 40 lb. or over, item 5 on a pressure of 40 lb., by adding addi-

CUT-OFF NECESSARY TO GIVE SAME POWER ON BACK PRESSURE AS AT ATMOSPHERIC EXHAUST, KEEPING I.S.P CONSTANT

FIG. 9

tional heating surface in form of coils to an amount as given by the formula

$$\frac{Ts \text{ at } 80 \text{ lb.} - T_P}{Ts \text{ at } 40 \text{ lb.} - T_P} - 1 = \frac{324 - 230}{287 - 230} - 1 = 65 \text{ per cent}$$

where Ts represents the temperature of steam and T_P the temperature of product.

Item 6 can be operated on a pressure of 40 lb. by adding additional heating surface in form of coils equal to:

$$\left(\frac{Ts \text{ at boiler pressure} - 240}{Ts \text{ at new back pressure} - 240} - 1\right) \times 100 = \text{per cent}$$

more.

Item 7 cannot be operated on any reasonable back pressure, hence a special line must be run here from the boiler pressure service mains. A test made by measuring the drip discharges from these apparatuses, however, gives a total value of steam consumed this way of only 3000 lb. per hour.

Item 8 can be run on 40 lb. by adding additional heating surface.

From Fig. 4 the necessary initial steam pressure to give same power on 65 lb. back pressure as on 105 lb. absolute exhausting to atmosphere is 185 lb. and the increase in weight of steam is 1.7. This can also be calculated from the steam tables, when increased steam weight will be proportional to increase of density

$$\left(\frac{4.24}{2.48} = 1.7\right).$$

Steam supplied engines at 185 lb. = 29,000 × 1.7	49,300
Steam condensed by expansion (Fig. 14), (Molier chart), (100 per cent — 93 per cent)	7 per cent.
Condensation losses	6 per cent
Total losses	13 per cent
Steam returned to factory by engines at 65 lb., 49,300 × (100 per cent — 13 per cent)	43,000
Steam required by factory at 65 lb.	47,000
Deficit to be made up by reduction value	4,000
Required by factory at 185 lb.	3,000
Total steam supplied by boilers at 185 lb., 49,300 + 4,000 + 3,000	56,300

Per cent saved, $\frac{79{,}000 - 56{,}300}{79{,}000} = 29$ per cent

This permits shutting down the 20 per cent low pressure boiler plant for economy. Thus by increasing the pressure on one bank of boilers we have succeeded in wholly eliminating the use of the other, thanks to high back pressure exhaust.

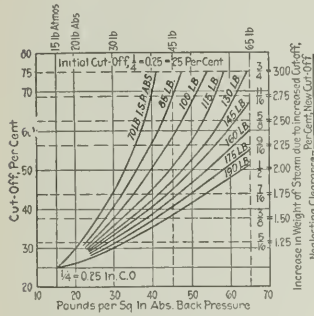

FIG. 10

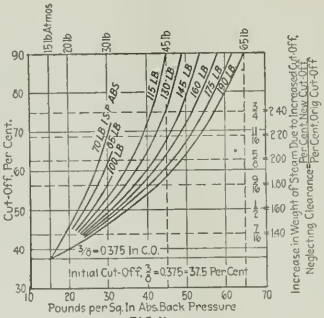

FIG. 11

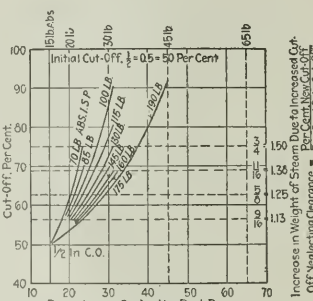

FIG. 12

CUT-OFF NECESSARY TO GIVE SAME POWER ON BACK PRESSURE AS AT ATMOSPHERIC EXHAUST, KEEPING I.S.P. CONSTANT

In order to illustrate the various use of the charts and calculations, three different conditions of the power plant will be assumed:

Case A—High back pressure obtainable by increasing initial steam pressure.

Case B—High back pressure obtainable by increasing cutoff of reciprocating engines.

Case C—High back pressure obtainable only by combination of the above.

Case A

High back pressure obtainable by increasing initial steam pressure: Assume a plant in which one-fifth of the total horsepower consists of H.R.T. boilers having a safe pressure of 100 lb. gage and the balance of water tube boilers having a safe pressure of 175 lb. gage. The average working pressure is therefore 90 lb. gage.

This case is typical of several plants which started to install high pressure boilers, but due to long deliveries and too rapid increase in production had to purchase something quickly, hence filled in with the low pressure H.R.T.'s.

Boiler pressure 400 kw. of Corliss engines at 35 lb./kw.-hr.	14,000
300 kw. slide valve engines at 50 lb./kw.-hr.	15,000
Hourly steam demand at atmospheric exhaust	29,000

Cut off from indicator cards = ⅛.

Case B

High back pressure obtainable by increasing cutoff of reciprocating engines: Boiler pressure on engines, 130 lb. Allowable boiler pressure, 140 lb.

Plant averages 400 kw. of Corliss engines at 35 lb. per kw.-hr	14,000
300 kw. of slide valve engines at 50 lb. steam per kw.-hr	15,000
Total average hourly steam demand for power	29,000

Cutoff from indicator cards = ⅛ (0.187 = 18.7 per cent)
130 lb. gage = 145 lb. absolute.

From Fig. 9:

Absolute Back Pressure, Lb. per Sq. In.	Cutoff for Same Power	Approximate Increase in Weight of Steam for Same Power
15	18.7	0 00
30	26.0	1.46
45	35.0	1.80
55	43.0	2.20
65	49.0	2 60

APPROXIMATE HIGHEST BACK PRESSURE TO UTILIZE ALL OF THE EXHAUST STEAM

	Per Cent.
Average expansion loss (equals moisture in steam at exhaust pressure, assuming dry and saturated at initial pressure can be read directly from Molier diagram, Fig. 14)	6
Average condensation losses	6
Total	12
Allow	3
Total	15

Steam consumption of factory which might be used on low pressure (15 to 65 lb.) = 50,000 — 3,000 = 47,000.

Steam consumption of engines = 29,000.

Proportion factory to engine consumption = $\frac{47,000}{29,000}$ = 1.62.

Adding 15 per cent for losses, factor becomes 1.62 × 1.15 = 1.87.

Most Economical Back Pressure

From Fig. 9 we see that the most economical back pressure is at the point of intersection of the ratio, value of 1.87 with the curve for 145 lb. = 45 lb. absolute back pressure (= 30 lb. gage) and 35 per cent cutoff. If sufficient additional heating surface can be put in the chemical apparatus to compensate for this reduced steam pressure, the problem is solved, the saving being approximated as follows:

Steam supplied to engines at 145 lb., 29,000 × 1.87	53,400
Loss due to expansion (Molier diagram, Fig. 14), (100 per cent — 92 per cent)	8 per cent
Loss due to condensation	6 per cent
Total loss	14 per cent
Steam supplied by engines to factory at 45 lb., 53,400 × (100 per cent — 14 per cent)	47,000
Steam demanded by factory at 45 lb., 50,000 — 3,000	47,000
Total steam supplied engines by boilers at boiler pressure	53,400
Total steam supplied factory by boilers for item 7	3,000
Total steam supplied factory by boilers under new conditions	56,400
Total steam supplied factory under original conditions	79,000
Saving	22,600

Per cent saving, $\frac{22,600}{79,000}$ = 28.6 per cent

Steam now chargeable to power, 53,400 × 14 per cent	7,400
Steam formerly chargeable to power	29,000
Saving	21,600

Per cent saving, $\frac{21,600}{29,000}$ = 74½ per cent

The method of attack when back pressure as found above is too low for the factory demands will be described below. Let us now examine the question of what pressure is necessary for the factory.

This is usually fixed by the highest temperature of product. The best way to proceed is to ascertain both by inquiries from the chemist and plant foreman and personal investigation just what is the highest temperature at which the products must be maintained. Also note whether the kettles are connected to a high or low pressure main and what is the average steam pressure at the jacket. Although the temperature drop and the heat transmission have been thoroughly investigated theoretically, yet the various differences in condition of heating surfaces and nature of materials renders proper application of the theoretical results difficult. The writer is doing a considerable amount of research on this point and may have results to publish later. For the present he has found a 50 deg. F. temperature drop to be sufficient in almost every case. Consequently the highest temperature of the product plus 50 deg. will give the temperature of the steam required in the jacket from which the necessary back pressure may be established. Having established this, the question of sizes of pipe and general steam calculations become easy.

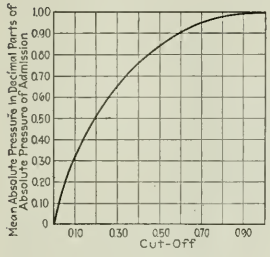

FIG. 13

STEAM ENGINE RATIOS

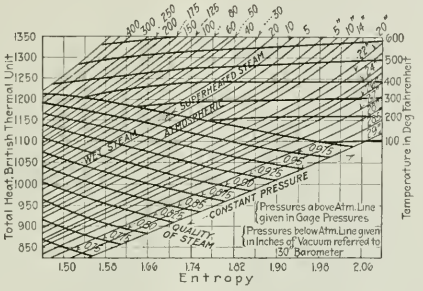

FIG. 14

MOLIER DIAGRAM

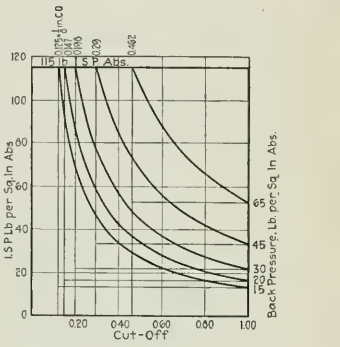

FIG. 15

EXPANSION CURVES SAME POWER AND I. S. P.

In special cases the value of the back pressure necessary may be determined by the economical pressure for the design of evaporating and cooking apparatus. Remembering that the rate of evaporating varies proportionately with the temperature differences and noting from the following table:

Pounds per Inches Abs.	Steam Temp., Deg. F.	Temp. Drop	B.t.u.'s per Sq. Ft. per Hour	Lb. Water Evaporated per Hour
15	212	0	0	0
20	228	16	8,000	8.4
30	250	38	19,000	19.6
45	275	63	32,000	33.0
65	298	86	43,000	44.5
70	303	91	. . .	. .
85	316	104	. . .	. .
100	328	114	. . .	. .
115	338	126	. . .	. .
130	347	135	. . .	. .
145	356	144	. . .	. .

We see, if we assume the case under consideration to be that of evaporating in an open vessel, that at a 50-lb. back pressure a given apparatus would do more than five times the work it would do at a 5-lb. back pressure, and similarly that a 50-lb. back pressure and a given apparatus would do about 70 per cent of the work it would do at a 100-lb. pressure.

The matter of the coefficient of heat transmission is a matter of conjecture varying greatly with the different conditions of evaporation. Theoretically the coefficient of heat transmission for iron is 233 B.t.u.'s per square foot per hour per degree temperature difference per inch in thickness. As evaporating and cooking apparatus is rarely over ¼-in. thick, this will give us approximately 900 B.t.u.'s per square foot per hour per Fahrenheit degree difference of temperature. Because

of the above variable conditions a good all around average value is 500 B.t.u.'s per square foot per hour per degree difference of temperature. This coefficient for heat transmission does vary greatly with pressure, according to Kerr in his article in the July, 1916, issue of the *Journal of the American Society of Mechanical Engineers*, page 545:

"Let V = coefficient of heat transmission in B.t.u.'s per square foot per hour per degree Fahrenheit, and let D = density of the heating steam in pounds per cubic feet, then: V = 225 + 17,500 D."

On the other hand, in a writers' discussion by Dr. Orrok, comparison was made with Parr's formulæ, where

$$V = 1290\sqrt{PD}$$

where P = absolute pressure in lb. per sq.in.

scale of Fig. 9, but may be calculated as follows: Assuming 65 lb. back pressure and 49 per cent cutoff we get the increase in weight of steam by engines = $\frac{49}{18.7}$ = 2.6

Hourly steam demand for power at 65 lb., 29,000 × 2.6	76,000
1 lb. steam expanding from 145 to 65 lb. will be (Molier diag. Fig. 14), 94 per cent dry at latter pressure	
Loss due to moisture (expansion), 100 — 94 per cent	6 per cent
Assuming 6 per cent condeosation loss	6 per cent
Total loss	12 per cent
Steam supplied by engines at 65 lb. to factory, 76,000 × (100 per cent — 12 per cent)	67,000
Steam required by factory at 65 lb	47,000
Excess steam supplied at 65 lb	20,000
Total steam under atmospheric conditions—power	29,000
Total steam under atmospheric conditions—factory	50,000
Total steam under atmospheric conditions, power-factory	79,000
Total steam under 65 lb. back pressure conditions, power-factory	76,000
Total steam factory at boiler pressure	3,000
Total steam from boiler under 65 lb. back pressure conditions	79,000

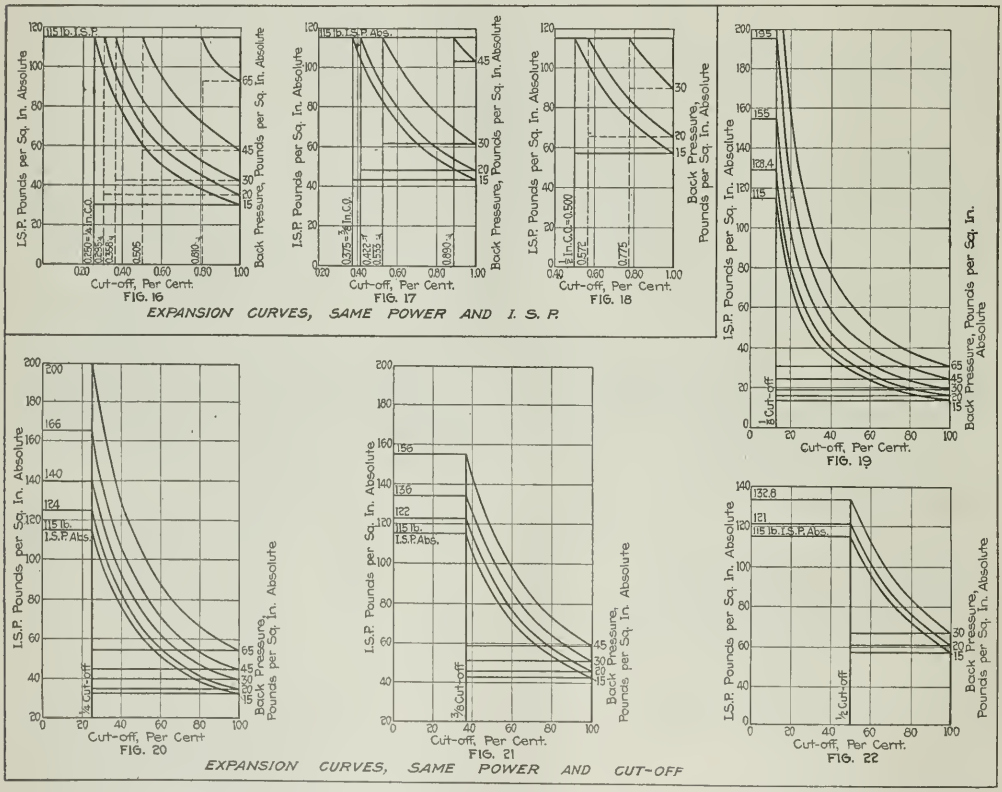

FIG. 16 FIG. 17 FIG. 18 FIG. 19 FIG. 20 FIG. 21 FIG. 22

Even with the lowest values by these formulæ, steam at 8-lb. gage pressure gives a coefficient V = 1200, which is too high and never reached in practice. The writer uses 500.

Method of Attack When Economical Back Pressure Cannot Be Used Because of Factory Conditions of Temperature

Assume a back pressure of 65 lb. absolute (equals 50 lb. gage) necessary for temperature conditions. The increase in steam will be approximately directly as the increase in cutoff. This is given as the ratio ordinate

Evidently for these conditions the gain is 20,000 lb. of steam for heating feed water at 65-lb. back pressure or for additional production, which in many ways would be well worth while. This system provides great capacity for heavy factory steam demand, as it could be said that there were 20,000 lb. of steam each hour which could be automatically diverted to the feed water heater or into the factory. It might be better, however, to run half the Corliss engine units (200 kw.) on an atmospheric feed water heater. The calculations then become:

200 kw. Corliss engines at 35 lb. kw.-hr.	7,000
300 kw. slide valve engines at 50 × 2.6	39,000
200 kw. Corliss engines at 35 × 2.6	18,200
Steam supplied to engines at 145 lb.	64,200
Steam delivered by engines to factory at 65 lb., (39,000 + 18,200) × 0.88.	50,300
Steam required by factory at 65 lb.	47,000
Excess for feed water heating and balance	3,300
Steam supplied engines	64,200
Steam supplied factory, at 145 lb.	3,000
	67,200

Saving of this system, $\frac{79,000 - 67,200}{79,000}$ = 15 per cent + 3,300 lb. for feed-water heating.

Amount chargeable to power, crediting power with 65 lb. feed water = 64,200 — (39,200 + 18,000) × 0.88 = 13,900.

Percentage of former amount $\frac{13,900}{29,000}$ = 48 per cent.

Amount chargeable to power, not crediting power with 65 lb. feed water = 64,200 — 47,000 = 17,200

Percentage of former amount, $\frac{17,200}{29,000}$ = 59 per cent.

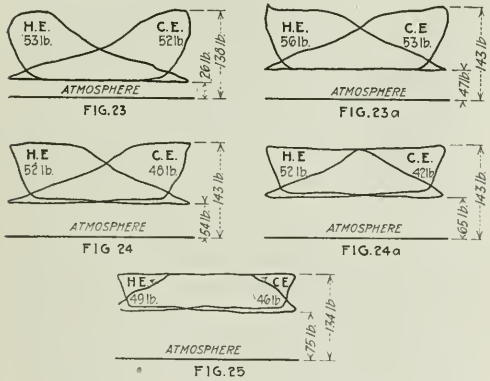
Case C

High back pressure obtainable only by combination of increased initial steam pressure and longer cutoff:

Working boiler pressure, 115 lb. gage equals 130 lb. abs.

Allowable boiler pressure, 150 lb. gage equals 165 lb. abs.

For same capacity and engine cutoff of ¼, from Fig. 4 the allowable back pressure will be increased from 15 lb.



FIGS. 23 TO 25. SOME SAMPLE INDICATOR CARDS TAKEN FROM AN ENGINE WORKING UNDER USUAL CHEMICAL PLANT NEGLECTFUL CONDITIONS, BUT WELL ILLUSTRATING THE ACTION AT VARYING BACK PRESSURES (FIGURES WITHIN THE DIAGRAMS ARE MEAN EFFECTIVE PRESSURES)

absolute to 33 lb. absolute by increasing the boiler pressure from 130 to 160 abs.

Ratio, $\frac{\text{Mean Absolute Pressure}}{\text{Initial Steam Pressure}}$ for 25 per cent cutoff = 0.586 (Fig. 13).

Mean absolute pressure = 160 × .586 = 93.8.

New back pressure (absolute) = 65 lb.

New mean absolute pressure = 93.8 + (65 — 33) = 125.8.

New ratio = $\frac{125.8}{160}$ = 0.785

New cutoff (Fig. 13) = 43 per cent.

Weight of steam per hp. will increase as its density, hence at 160 lb. will be $\frac{3.46}{2.84}$ = 1.22 times its weight at 130 lb. It will also increase directly as the percentage cutoff (neglecting clearance), hence at 43 per cent cutoff will be $\frac{43}{25}$ = 1.72 times its weight at 25 per cent cutoff. The total increase in weight of steam therefore will be 1.72 × 1.22 = 2.10. This value is high, because of the assumption made.

One lb. of steam expanding from 160 to 65 will be 94 per cent dry (Molier chart, Fig. 19) at the latter pressure. Allow a value of 6 per cent for cylinder condensation and leakage losses, and we have:

Total steam delivered by boilers to engines at 160 lb. pressure, 2.1 × 29,000	60,800
Total steam delivered by engines to plant at 65 lb., 2.1 × (0.94 — 0.06) × 29,000	53,500
Steam chargeable to power	7,300
Percentage of steam formerly used for power, $\frac{7,300}{29,000}$ = 25 per cent	
Total steam required by factory at 65 lb., 50,000 — 3,000	47,000
Total steam delivered by engines at 65 lb.	53,500
Excess steam for feed water heating at 65 lb	6,500
Steam required by factory at boiler pressure for item 7 (115 lb. gage—atmospheric)	3,000
Total steam under old conditions, 50,000 + 29,000	79,000
Total steam under new conditions (145 lb. gage to 50 lb. gage), 60,800 + 3,000	63,800
Saving in total steam, new as compared to old conditions	16,200

Per cent saving, $\frac{16,200}{79,000}$ = 21 per cent

Other Savings

When electricity is bought the substitution of cheap slide valve engines will often show a remarkable saving, when all the exhaust steam can be utilized in one of the ways shown above. For example, assume electricity at 2 cents per kw.-hr. and steam at 25 cents per 1000 lb.: Steam per kw.-hr. through engine, 50 × 1.75 = 87.5 lb. Steam used for power per kw.-hr., 87.5 × 0.12 = 10.5 lb.

Cost of steam per kw.-hr., $\frac{25 \times 10.5}{1000}$ = 0.262 of 1 cent.

Saving in power bill, $1 - \frac{0.262}{2000}$ = 87 per cent, which must be decreased by wages of engine room force, oil and supplies and interest and depreciation on engines (but engine room alone—*not* boilers).

Fifty pounds is sufficient pressure to run steam-driven duplex pumps under average conditions met in chemical plants. Where this does not result in sufficient pressure, a cheap remedy is to introduce liners in the liquid cylinders of the pump.

Superheat—Theoretically the ideal superheat to use is just sufficient to provide dry and saturated steam after expansion in the engines. Usually this means a total temperature of 550 deg. F. to 600 deg. F. As the average chemical plant is not operating with superheat to-day, no example is here given, but same can be readily solved by means of the charts.

Additional Cost of Increased Pressure

In some of the above examples the solution involves a slight increase of boiler pressure. Although theoretically this implies a corresponding increase in coal burned, yet experience has shown that this factor, if present, is so negligible as to be indistinguishable. In other words, no more coal is burned, in testing under normal plant conditions, to deliver one pound of steam at the higher pressure than at the lower, within the limits above indicated.

In 1915 one of the writer's plants was confronted with the following problem:

Three 200-hp. H. R. T. boilers good for a maximum

pressure of 150 lb. gage were supplying the factory. Due to the large amount of steam required, they were unable to maintain the pressure of 125 lb. The factory pressure was normally between 60 and 90 lb. It was also supplied with 150-hp. boilers, good for a maximum pressure of 90 lb. gage. The proposal was made to combine these with the H. R. T. boilers and run in that unsatisfactory way at about 85 lb. gage.

Instead of this a back pressure of 40 lb. per sq.in. gage was decided upon and the three high pressure H. R. T. boilers were operated at a pressure of about 140 lb. The 90-lb. boilers were used when necessary to make up for extra load through a reduction valve to bleed low pressure steam into these 40 lb. back pressure mains. Since that time the load on the boilers has been increased nearly three times, and although hand fired the high pressure mains vary between 125 and 140 lb., averaging 135 lb., and the low pressure mains are held practically constant at 40 lb. The result has been a great economy of fuel, ability to operate not only when lack of boiler capacity apparently prevented operation, but also after a considerable increase in the chemical apparatus load. A saving of many thousands of dollars has been accomplished.

Summary

The charts show very clearly the great advantages of having as high as possible initial steam pressure, and furthermore indicate the way to increase the present steam pressure by adding higher pressure units gradually, retaining the lower pressure to assist the back pressure exhaust system.

The higher the initial steam pressure the higher back pressure may be, with smaller pipes and less cost for installation of both. A comparison of pipe sizes is given below:

COMPARISON OF PIPE SIZES

40 lb. gage back pressure requires a pipe	7.82 / 23.80	or 32.9 per cent. of pipe required for 2 lb.
40 lb. gage back pressure requires a pipe	7.82 / 19.45	or 40.2 per cent of pipe required for 6 lb.
40 lb. gage back pressure requires a pipe	7.82 / 3.89	or 203 per cent of pipe required for 100 lb.
40 lb. gage back pressure requires a pipe	7.82 / 3.12	or 251 per cent of pipe required for 130 lb.
40 lb. gage back pressure requires a pipe	7.82 / 2.84	or 277 per cent of pipe required for 145 lb.
50 lb. gage back pressure requires a pipe	6.68 / 23.80	or 28 per cent of pipe required for 2 lb.
50 lb. gage back pressure requires a pipe	6.68 / 19.45	or 24.3 per cent of pipe required for 6 lb.
50 lb. gage back pressure requires a pipe	6.68 / 3.89	or 172 per cent of pipe required for 100 lb.
50 lb. gage back pressure requires a pipe	6.68 / 3.12	or 214 per cent of pipe required for 130 lb.
50 lb. gage back pressure requires a pipe	6.68 / 2.84	or 235 per cent of pipe required for 145 lb.

The utility of high-pressure exhaust steam is evident. In general, wherever the factory use of steam is approximately equal to the power use, low pressure exhaust steam should be used. A factory use of steam of about double the power use or greater will usually justify the highest pressure exhaust steam. Between these limits the economical back pressure will vary as explained above. Because of the many different conditions to be found, further summarization has not yet been thought advisable in this paper, intended only to explain the accompanying charts, as in using them the reader will naturally form his own conclusions.

In so far as this type of chemical plant is concerned, the writer believes the ideal condition of operation is as given in Fig. 26. This assumes that the highest pressure required for the factory processes is 65 lb. absolute, which the writer has found to be true in his plants so far. In those chemical plants where a higher pressure is required, it will be necessary to modify Fig. 26 accordingly.

The steam is generated at a pressure of from 200 to 300 lb., and because of the usual operating conditions the boiler house is a considerable distance from the center of the steam load. Transmission of steam is through a comparatively small pipe, utilizing high velocities. A reduction valve at the receiving end permits rapid and large fluctuations of the steam pressure at the boiler, without affecting the pressure at the engines. These fluctuations may be due to irregularities in firing

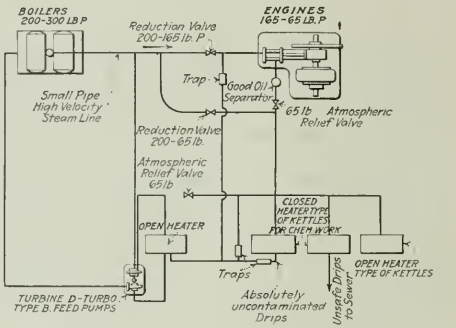


FIG. 26. STEAM LAYOUT FOR CHEMICAL PLANT

and to sudden fluctuations in the demand; the latter are exaggerated because of the smallness of the pipe. This valve, furthermore, tends to dry the steam just before it enters the engines.

The engine exhausts at 65 lb. absolute, and after passing through a good oil separator, the steam is carried to the chemical processes, where it is consumed in one of three principal types of steam consumers. In one, the closed heater type of kettle, the steam is never in contact with the material in the kettle, nor is there any danger to be expected therefrom. Usually this is a heater in which the chemical is never under pressure. The second type is also a closed heater, but as the pressure of the chemical may at some time or other be greater than the pressure of the steam, the drips must be considered unsafe, and either wasted to the sewer or utilized in some other way wherein there is no danger of contaminating the boilers. The third type is the open heater type, in which the steam is actually made a part of the liquid it heats. A closed type boiler feed water heater is also included in both sketch and above description as part of type one, in order to balance any excess steam at 65 lb. Under certain conditions it would be advantageous to use some type three heaters as the supply for boiler feed pumps.

The remainder of the system is evident. It is to be noted, however, that because of the two atmospheric relief valves and two reduction valves, steam pressures must remain practically constant on both the initial and the exhaust steam side of the engines, regardless of the conditions of steam production or of steam consumption.

Influence of Gypsum on the Blast Furnace Slags in the Manufacture of Cement

A Report on the Granulated Slag-Lime-Gypsum Composition Cements as Developed In Russia—Resistance to SO Ion Has Demonstrated Value In Construction Subjected to Sulphate Corrosion

By EUPHIME BERESLAVSKY

ACCORDING to the German patent No. 159,866, "for the preparation of binding materials such as portland cement, damp granulated blast-furnace slags were mixed with unslaked lime and the dry mixture obtained was reduced to powder. However, experiments proved that by applying this method the hydraulic qualities of the grains of slags can be used only superficially. In order to utilize them fully, the mixture of blast-furnace slags and unslaked lime is subjected to the action of elastic steam, after which the mixture is ground. Usually it is necessary, before grinding, to dry the mixture, after subjecting it to the action of elastic steam. In order to avoid this, the granulated slags are first subjected to the action of steam separately and afterward are mixed with the necessary quantity of unslaked lime. Thus a dry mixture is obtained, which is reduced to powder without preliminary drying in mills. The powdered product, which looks like portland cement, is then used in the same way as the latter."

As is evident from this brief synopsis, this German patent is a method of obtaining a binding material, which hardens in water, from the granulated blast-furnace slags and unslaked lime.

The general method of producing binding material (slag cement) is based on the addition of the necessary quantity of hydrated lime to the dried and granulated slags. The addition of lime depends upon the coefficient of the co-relation of the sum of alkali to the acids.

According to the above:

Composition of Slags Used	Per Cent	Composition of Cement Produced	Per Cent
CaO	41.5	CaO	45.4
MgO	3.2	MgO	2.8
SiO_2	42.0	SiO_2	35.7
Fe_2O_3	0.6	Fe_2O_3	0.9
Al_2O_3	10.8	Al_2O_3	9.7
S	1.5	S	1.4
Insoluble residue	0.4	Insoluble residue	0.5
		Loss on ignition	3.6

The tensile strength of this cement:

	Pure Kg. per Sq.Cm.	With Sand (1 Part to 3 Parts), Kg. per Sq.Cm.
After 1 day	9.6	
After 7 days	31.2	10.5
After 28 days	38.2	24.5
After 3 months	....	29.9

Tensile Strength

The tensile strength of the cement is to a certain degree (2.0 to 2.2), according to Tenmayer, proportionate to the coefficient of the co-relation of the sum of alkalis to the acids. This coefficient of the slag, on which I experimented as above, was:

$$\frac{Al_2O_3 + CaO + MgO}{SiO_2} = \frac{9.8 + 42.6 + 1.1}{25.6} = 2.1$$

The slag, preliminarily dried and then ground in the rotary mills, was sifted by me through sieves with 4900 holes per sq.cm.

The average tensile strength (according to Mey) of the normal slag cement should be:

After 7 days	14 to 19 kg. per sq.cm.
After 28 days	20 to 27 kg. per sq.cm.
After 84 days	25 to 30 kg. per sq.cm.
After 210 days	29 to 35 kg. per sq.cm.

Breaking Stress of Normal Slag Cement

The average breaking stress of the normal slag cement (according to Mey):

After 7 days	105 to 133 kg. per sq.cm.
After 28 days	170 to 221 kg. per sq.cm.
After 84 days	220 to 260 kg. per sq.cm.
After 210 days	240 to 288 kg. per sq.cm.

In general, slag cement has less tensile strength than portland cement; however, in admixture with sand it gives reverse results. The setting of slag cement should not be as quick as that of portland cement, and in general the process of hardening should be slower. For instance, the Ashland Pozzolanic cement begins to set within 3 hours and 40 minutes and finally sets within 8 hours.

Matezius' experiments show that the granulated slag changes owing to the influence upon it of elastic steam in a closed vessel, and the mass crumbles and forms a dry powder—a cementitious and hydraulic product.

Although the conditions and nature of work unfortunately did not permit me to test it, yet I presume that if the process of slaking of lime (producing quicklime) is done in a closed vessel in connection with the process of obtaining the dry cementitious powder "matezius" from blast-furnace slags, a strong fusing material (stronger than slag cement) will be obtained if these processes are properly carried out. This, in my opinion, requires special attention.

Lime Does Not Affect Hydraulic Qualities

The quantity of lime added to the slags has no great bearing on the resistance of cement. There may be added 10 to 25 per cent of the entire weight of dry slag. To a good quality of basic slag 10, 15, 20 or 25 per cent of lime may be added without a noticeable change in its hydraulic properties. I believe that the most suitable coefficient for slag cement is about 1.9. Magnesia, of which there is in slag cement sometimes as much as 30 per cent, does not affect the hydraulicity of cement, although there is an opinion that magnesia in combination with gypsum is the cause of inconstancy of volume of cement solutions. The cementitious solution obtained from slags is of a greenish color, which is ex-

plained by the following: The slags contain sulphur in the form of MnS, CaS and $CaSO_4$ (altogether to the amount of 1 to 3 per cent). When granulating:

$$CaS + 2H_2O = Ca(OH)_2 + H_2S$$
$$3H_2S + Fe_2O_3 = 2FeS + 3H_2O + S$$

FeS gives the slag a greenish color. FeS does not affect the properties of cement; samples of it, having a very dark color, did not change in volume after being kept under water for a long time. On the other hand, in the open air it loses all color and becomes white owing to the oxidation of FeS into $FeSO_4$. $CaSO_4$ does not act detrimentally upon the properties of cement, but merely changes the speed of setting.

The tested granulated slag, which gave by itself, without addition of other materials, a breaking stress of less than 4 kg. per sq.cm. after 28 days, upon addition of quicklime (CaO) gave the following results:

90 PER CENT SLAG + 10 PER CENT CaO

Age at Test	Batch Number	Tensile Strength, Kg. per Sq.Cm.	Age at Test	Batch Number	Tensile Strength, Kg. per Sq.Cm.
7 days	1	12.9	28 days	1	36.7
	2	12.7		2	36.2
	3	13.5		3	34.5
	4	14.0		4	38.5

Hydraulic modulus 1.4.
Setting of the slag cement obtained begins after 32 minutes.
Final set within 3 to 4 hours.
Normal consistency of the solution is 31 per cent.

90 PER CENT SLAG + 2 PER CENT RUSSIAN (GLUKHOOZERSK) PORTLAND CEMENT + 10 PER CENT CaO

	Batch Number	Kg. per Sq.Cm.
After 7 days	1	14.5
	2	13.9
	3	13.6
	4	14.0

From this we gather that the admixture of a small quantity of portland cement does not affect the strength of the cement.

BREAKING STRESS

	Batch Number	Kg. per Sq.Cm
Cube with 10 per cent CaO with sand	1	198.6
	2	142.3

TENSILE STRENGTH

One part (90 per cent slag + 10 per cent CaO) to 3 parts standard sand.
Normal consistency of the solution is 9½ per cent water:

	Batch Number	Kg. per Sq.Cm.
After 18 days	1	23.6
	2	23.2
	3	24.1
	4	24.8
	5	20.4
	6	21.4

Storage of briquets—1 days in moist air, 17 days in water.
One part (90 units slag; 2, portland cement; 10, CaO) to 3 parts of standard sand.

	Batch Number	Kg. per Sq.Cm.
After 18 days	1	20.3
	2	18.1
	3	19.2
	4	23.0

As shown above, the strength of the mixture of slag with portland cement is even somewhat smaller than without it.

Mixture of 1 part slag + 25 per cent quicklime, hydraul. modul., 1.93.

THE TENSILE STRENGTH OF BRIQUETS

Normal consistency for 1 part cement and three parts standard sand = 9½ per cent water.

	With Sand — Batch Number	With Sand — Kg. per Sq.Cm.	Without Sand — Batch Number	Without Sand — Kg. per Sq.Cm.
After 28 days	1	150.2	1	284
	2	166.3	2	300
	3	148.7		

One day in moist air, 6 and 27 days in water.

THE BREAKING STRESS (WITH SAND)

Age at Test	Batch Number	Tensile Strength Kg. per Sq.Cm.		Age at Test	Batch Number	Tensile Strength Kg. per Sq.Cm.	
After 7 days	1	13.6	About 200 lb. per Sq.In.	After 28 days	1	28.7	About 400 lb. per Sq.In.
	2	12.0			2	26.7	
	3	12.7			3	26.9	
	4	13.8			4	27.8	

One day in moist air, 6 and 27 days in water.

THE BREAKING STRESS (WITHOUT SAND)

Normal consistency, 34 per cent water.

	Batch Number		
After 7 days	1	27.5 kg. per sq.cm.	About 400 lb. per sq.in.
	2	26.3 kg. per sq.cm.	
	3	28.0 kg. per sq.cm.	

That is, higher than normal, 20 kg. per sq.cm.

	Batch Number		
After 28 days	1	50.2 kg. per sq.cm.	About 650 lb. per sq.in.
	2	47.4 kg. per sq.cm.	
	3	46.2 kg. per sq.cm.	
	4	42.6 kg. per sq.cm.	

That is, higher than normal, 25 kg. per sq.cm.

The cement manufactured by the Russian portland cement works gives:

	Pure	Mixture
After 7 days	About 35 kg. per sq.cm. (About 500 lb. per sq.in.)	About 12 kg. per sq.cm. (170 lb. per sq.in.
After 28 days	About 45 kg. per sq.cm. (About 650 lb. per sq.in.)	About 16 kg. per sq.cm. (225 lb. per sq.in.)

Thus we can see that the cement obtained from the slags, which I tested, of the Alexandrovsk South Russian Works of the Briansk Co., without sand, was approximately equal in strength to the portland cement, and with sand even exceeded it. The cakes made of this cement had proved the constancy of its volume. Consequently, the above granulated basic slag had proved to be a suitable material for the production of slag cement of high quality.

At the beginning of the activity (1913-1914) of the above-mentioned slag works (reorganized) I had an interview with the director and supervisor of the chemical laboratory of the works and during the interview I stated my plans of working with their slags. In the summer of 1914 this plan was tried in the laboratory of these works, and later on in the shops, and gave good results. In 1917, when I visited the works, they were at the height of their productivity. Wishing to make a further study of the properties of slag and of its interaction with lime and gypsum, I applied the mathematical rule of combination of these elements.

Combinations That Are Possible

The following combinations are possible:

Elements:

1. Granulated slag.
2. Non-granulated, or, more correctly, degranulated slag.
3. Lime (quicklime).
4. Gypsum (burnt and semi-hydrous).

Possible combinations of the four elements, in twos (C_4^2):

1 and 2	2 and 3	3 and 4
1 and 3	2 and 4	.....
1 and 4	.....	.....

Combinations of the four, in threes (C_4^3):

1	2	3	2	3	4
1	3	4	2	1	4

There can be no other combinations.

Five Useful Combinations

Excepting the combinations that are useless for us, 1 and 2, 2 and 3, 3 and 4, 1, 2 and 3 and 1, 2 and 4, we have five combinations, which will serve me for my investigations. If we set aside the combination of granulated slag with lime (1 and 3), already tested, only two binary mixtures remain:

(a) Granulated slag with gypsum.

(b) Degranulated slag with gypsum.

Two ternary mixtures remain:

(a) Granulated slag with lime and gypsum.

(b) Degranulated slag with lime and gypsum.

By "degranulated" I mean the granulated slag, which I had, and in which all granulation properties had been eliminated by means of preliminary heating up to a high temperature and subsequent slow cooling in a closed kiln.

In the fusion of slag and gypsum there can finally take place such a co-relation of the component parts of the combination that it would resemble the so-called "cement bacillus," to which Candlot and Deval have given the formula Al_2O_3, 3CaO, $3CaSO_4$, 28.4 H_2O. This fusion after the hardening of the cement solution produces a large increase of volume. A small quantity of burnt gypsum, on the other hand, acts beneficially. Without altering the volume it retards the setting of the cement and increases its strength.

Finding Most Favorable "State of Balance"

The retardation of the setting is explained by the fact that burnt gypsum does not enter into interaction with $CaOH_2$. The formation of "cement bacillus" destroys this retarding influence in the setting. The finding of the most favorable "state of balance" of the component parts of the mixture of slag and gypsum is the fundamental problem of our theme. The answer can be given only approximately and as applied to the slag used in the test.

There are indications that by partial addition of gypsum to granulated slag it was possible to obtain a tensile strength of 43 kg. per sq.cm. after 28 days, but the amount of the addition and the co-relation of the gypsum elements to the others I have not been able to determine. From my investigations I would say that the addition of 10 to 15 per cent of gypsum is the most suitable, although I was not successful in obtaining thereby a very high strength in the cement.

Adding from 1 to 25 per cent to our slag we gradually approach Deval's formula, but to reach this formula absolutely, without the introduction of alumina, is impossible, as can be seen from the chemical analysis of the slag tested. By adding 25 per cent of gypsum the following compound is obtained:

Al_2O_3	CaO	$CaSO_4$
1	3	4

Combinations with this amount of $CaSO_4$ (25 per cent) and a little more (30 per cent to 35 per cent) produce negative results.

Thus cubes made of a combination of degranulated slag with 25 per cent of gypsum gave after 28 days a breaking stress of only 63 kg. per sq.cm. and tensile strength of 7.4 kg. per sq.cm. Eight-shapes of the same mixture, but with sand, gave a breaking stress after 28 days of 4 kg. per sq.cm., a slag being used in which granulation had been eliminated by means of preliminary heating up to a temperature of 1280 to 1300 deg. (No. 9 = 10 Zeger pyramid) in a gas kiln and subsequent slow cooling in a closed kiln.

Some of the briquets composed of (1) granulated slag with 5 per cent of gypsum, (2) degranulated slag with 5 per cent of gypsum, placed in water became quite soft after two days, and part disintegrated and turned almost into mud. Those of the briquets that, after remaining two days in a moist place (above water), had not been put in water, but were left for several days in the open air and then for experiment put in water, disintegrated entirely within a few hours.

Samples made of 85 parts of granulated slags to 10 parts of quicklime to 5 parts of $CaSO_4$ and 85 parts of degranulated slags to 10 parts of quicklime to 5 parts of $CaSO_4$ had swelled, cracked and changed their volumes (just as slags of same composition but with sand) after being in water for 7 days.

Effect of Adding Gypsum

Consequently, slag cement (even with an enlarged hydro-modulus) made of granulated slag and 10 per cent of quicklime, which had, as shown above, a good stress, lost its stress on addition of 5 per cent of burnt (and semi-hydrous) gypsum and also changed its volume.

When I repeated the experiments, keeping to the addition of 4 to 6 per cent of well-burnt gypsum continuously to the granulated slag and slag wherein granulation had been eliminated, the results were the same. After two days the briquets with sand, which had been lying in water, disintegrated entirely, part of briquets (without sand) changed in volume, having swelled and formed large cracks, while the slightest contact broke them up. The final hardening of the samples was sometimes not noticeable even after two days, and a touch of the finger left a mark. Other samples broke up by themselves, not having hardened completely.

With the increase of the amount of gypsum added up to 10 to 12 per cent of the total weight of the mass, the fusing properties of the hydraulic mixture began to appear thus:

90 parts of degranulated slag to 10 per cent $CaSO_4$ (burned) gave the following average:

	Batch		
After 7 days.....	1	10.2 kg. per sq.cm.	Or about 150 lb. per sq.in.
	2	10.7 kg. per sq.cm.	
	3	10.3 kg. per sq.cm.	
	Batch		
After 28 days.....	1	23.7 kg. per sq.cm.	Or about 350 lb. per sq.in.
	2	24.2 kg. per sq.cm.	
	3	22.4 kg. per sq.cm.	

When 15 per cent of $CaSO_4$ was added to the total weight of the mixture the resistances were about the same. After further additions, however, the resistances in my experiments began to fall. No change of volume was noticeable. Parts of matte cement remained firm and hard and showed no signs of distortion, cracking, checking or disintegration in the steam test for soundness. The beginning and final setting I tested with the Vicat apparatus. Setting commenced on the average after 15 to 25 minutes and final setting took place after a few hours.

How Lime and Gypsum Influence the Constancy of Volume and the Setting of Cement

We shall now consider lime and gypsum as factors influencing the constancy of volume and the setting of cement.

According to Dr. Kuhl's report before the Society of German Manufacturers of Portland Cement in 1912,[1] the increase of volume $Ca(OH)_2$ during the hydration of the component parts of the cement clinker produces inconstancy of the fusing material. This, however, does

[1]Russian Journal "Cement," Vol. I, 1914.

not always happen. Kuhl's supposition was that the hardened cement has a certain space for the formation of $Ca(OH)_2$; that is, certain processes take place in connection with the reduction of volume, thereby creating the necessary space for the appearing hydrate of lime. In hardening, one part of the lime changes into hydrate, while the other part forms hydraulic silicates and aluminate. These processes act as if in completion of one another and in certain co-relations no change of volume takes place. The resistances within the paste are then equalized by counter forces outside. As is known inconstancy of volume is also the result of a too great content of gypsum. This is considered by Kuhl in the same light as the above in connection with the decrease or increase of volume during the hardening of the cement. The hydrate of the lime in this instance is substituted by sulpho-aluminate lime (according to Le Chatelier Al_2O_3, 3CaO, $3CaSO_4$, 28.4 H_2O), or as Michaelis calls it, "cement bacillus," formed of gypsum and hydraulic aluminate of lime.

As I have remarked, the inconstancy of volume is caused by the content of too much gypsum; it does not follow, however, that gypsum is always harmful, as it changes the volume in hardening. On the contrary, where there is not a sufficient amount of hydrate of lime to obtain high strength and not all the free space in the thick of the lime is filled by it, the presence of "cement bacillus" is indeed very useful, as it fills up the space remaining empty.

Therefore, reviewing the inconstancy of volume of cement in connection with gypsum, we must consider it as depending not only upon the amount of gypsum itself, but also in a great measure upon the amount of lime in the cement.

Placing the content of gypsum in the cement in connection with the amount of lime, Dr. Kuhl cited a number of examples proving that as a matter of fact with a low hydro-modulus of portland cements, as for instance, with a hydro-modulus of 1.85, 6 per cent of $CaSO_4$ is required, while with a hydro-modulus of 2.3 only 0 to 1½ per cent is necessary for best strength with no modification of volume.

It is now considered as proved that inconstancy of volume from gypsum depends not on the absolute amount of lime, but upon the relation of gypsum to lime, and that this is especially observed in cements obtained from blast-furnace slags. According to Kuhl, blast-furnace slag granulated in water, with an addition of 3 per cent of gypsum, after 28 days (hardening under water in mixture with sand 1 part to 3 parts) had a tensile strength of 6 kg. per sq.cm. and breaking stress 38 kg. per sq.cm. Owing to the increased addition of gypsum, the 28 days strength of the hydrated samples grew progressively for tensile strength, 27 and 40 and 43 kg. per sq.cm., and for breaking stress, 196 and 412 and finally 604 kg. per sq.cm.

As has been remarked by Kuhl (this has been corroborated by builders in the south of Russia in port construction in the Azov and Black Seas), the relation of cements with poor content of lime to gypsum makes them especially suitable for marine construction; as the cement is the less sensitive to the acid substances of sea water the more gypsum the cement can take in without disturbing the constancy of volume. The more lime is substituted by gypsum, the more suitable will the cement be for marine construction.

Cements that require considerable amounts of gypsum (10 per cent and more) in order to evidence good properties become immune from the destructive action of sulphuric acids; they are inoculated, so to speak. The corresponding action of the gypsum that forms subsequently will be the weaker according as more gypsum is contained in the cement originally.

Conclusion

Cement prepared with a corresponding co-relation of gypsum and slag and properly prepared can be used in the construction of quays, cisterns, reservoirs, canals, bridge supports, etc. When used for molding stones and artificial marble, which may break by rapid drying, they should at first be moistened.

In conclusion I wish to mention the following additional points:

1. Various cements obtained from blast-furnace slags, when they are the most important component parts (in per cent) of the raw material obtained, cannot and shall not be accepted on the general rules applied to ordinary portland cement. For the acceptance of above mentioned cements the content of sulphuric anhydrate (SO_3) in them must be found in a quantity of more than 2 per cent and even in higher quantities in order to secure their physical and mechanical properties and their resistances, as demanded by the standard regulations for portland cement.

2. A change of this sort makes it possible to utilize properly, without endangering the strength of the buildings, those rather large quantities of slags which have accumulated during the war at the metallurgical works and which cannot be worked into cement in any other way.

Although such cement would not answer in its chemical composition to the standard international specifications, a very fine and cheap cement could be obtained from these slags if the manufacture of it is properly organized.

The Present Status of Oil Shales

MUCH publicity of various sorts has recently been accorded the huge deposits of oil shales occuring in the Uintah Basin, occupying the northeastern portion of Utah south of the Uintah Mountains and extending eastward into Colorado. A less-known region of western Wyoming occupying the Green River Basin northward from the Uintah Mountains to the Wind River Mountains probably contains an even greater area of oil shale beds. A third deposit of enormous size lies astride the Colorado-Wyoming border sixty miles further east.

In addition to these tremendous and only roughly-mapped regions, an area of about 2500 square miles of good oil shale has been located in the central part of Utah, near Manti. Near the station of Elko, Nevada, on the Western Pacific Railroad, occurs a relatively small area upon which many locations have been made. In fact patches of oil shales up to 100 square miles in extent may be found at numerous spots all over the Rocky Mountain region. These are in addition to the numerous small areas of asphaltic sandstones (popu-

larly known as "oil sands") scattered through the Western plateau, in area up to a few townships. Of the latter, a well known and large irregular deposit occurs in the San Raphael swell 60 miles south of Price, Utah, and another near White Rock in northeastern Utah.

Superficial Appearance

The shales themselves vary greatly in superficial appearance as well as in physical properties. Thus, the color, specific gravity and yield change in perfectly discontinuous fashion, so that about the only generalization one may make is that eye-examination tells nothing as to the possibilities of the sample. Broadly speaking, it may also be said that differences in appearance are

FIG. 1. HELL'S HOLE CANYON, NEAR WHITE RIVER, UTAH

regional rather than stratigraphical; the layers in a bed at a certain locality frequently look much alike, but may vary greatly in oil content. As is only natural from the wide distribution and immensity of the deposits, the amount of lean overburden above the workable seams is also subject to large variation. Usually oil-shale beds will be exposed on the high, steep-sided bluffs cut by river erosion, as is shown in Fig. 1, while the back country shows few outcrops; in general the rolling surface consists of more or less disintegrated rock, quite often of shale which has lost but little of its original carbonaceous matter by atmospheric oxidation. Sometimes rivers have carved valleys hundreds of feet deep through kerogen-bearing strata without reaching barren material. It is also fortunate that the areas were not folded to any great extent in their upheaval from the ocean bed, nor are they buried to any depth under other sediments of more recent date. In this as well as many other characteristics our Western shales are so different from those treated by the oft-quoted Scottish industry that analogies cannot be drawn safely.

Nature of Kerogens

The geological origin of the shales is a matter of considerable interest, but as yet the problem has not been definitely solved. Since there seems to be a complete and unbroken series from lean oil shales to lignites, information on such coals should be illuminating. According to Potonié and Heinold, non-bituminous lignite coals were formed at regions where extensive subtropical flora grew in swamps and where the remains of this vegetation accumulated into a peat bog. Sand or clay then collected during a subsidence of the ground, and this impervious covering protected the carbonaceous deposit from entirely rotting away. The bituminous lignites were formed in the same regions during droughts, when the cellulose exposed to the air decomposed to water and carbon dioxide, while the fats and wax resins remained intact. Bituminous shales were formed largely of these unoxidized organic remains swept down by rivers into a deep, quiescent lake or arm of the sea. Many traces of animal life have also been identified in oil shales; Western shales also contain more or less carbonate, probably organic in origin. Thus, these complex hydrocarbons, the remains of animal and vegetable life, were deposited during the building of the sedimentary beds by the accumulation of the smallest particles of inorganic sediment—largely calcium, magnesium and aluminium silicates. During the long stretch of time the beds became of tremendous thickness, and eventually, by a change in the geological conditions, were overlain by other sediments carrying no carbonaceous matter, and pressure-metamorphosed into shale beds (Fig. 2).

One great distinction holds between the oil-forming materials of shale and bituminous lignites, however, which is not explained by the preceding theory. This is that the bitumen in lignite is soluble in many common organic liquids, such as benzol, alcohol and carbon disulphide, while the carbonaceous materials of Messel coal and oil shales (particularly Scottish shales) are not soluble to any great extent. The definition of the term "bitumen" has consequently been stretched to cover all substances which furnish oils and tar when subjected to dry distillation. Brown's suggestion is better: Call the organic remains in shales "kerogens," since they are substances capable of producing oils, and yet are apparently neither bitumen, petroleum nor resin.

Foreign vs. American Processes

Bituminous lignites and shales have been retorted in Germany, Scotland and France for many years. Each material produces a variety of gaseous and oily fractions, together with solid paraffines and coke. Even with the

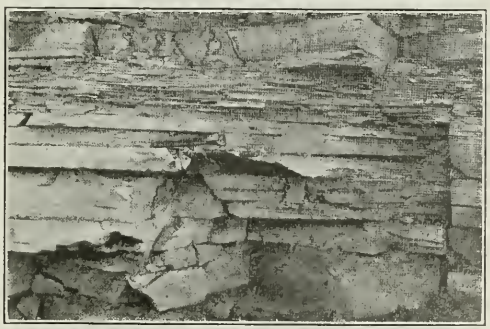

FIG. 2. CLOSE VIEW OF AN OIL SHALE FORMATION
(Courtesy of the D. & R. G. Ry.)

low price of foreign labor, the sale of the coke resulting from lignite-retorting is the return which keeps these enterprises alive; while the Scottish shale industry exists by virtue of the ammonia recovered as a "by-product." In the development of these foreign processes almost every conceivable type of retort was "invented," and many of them tried in practice. The early investi-

gators soon found themselves on the horns of a dilemma —intermittent retorts successfully produced gas, oil and coke, but were of very low capacity. On the other hand continuous retorts gave bigger tonnage but an incomplete recovery, and the oils produced were of low quality. Many trials resulted in the survival of gas-heated vertical retorts lined with iron and brick, with a slowly descending charge column. By means of heating flues built in the sidewalls of the shafts, the temperature is closely controlled; indeed, such regulation is absolutely essential for the production of satisfactory volatiles and residues.

Apparently the first thing which an American does when he discovers the existence of oil shale is to invent a process or furnace for getting the oil. Scores of patents have been issued, but it is doubtful if many of them are commercially plausible, and questionable whether the best of these present any improvement or addition to previous knowledge which will withstand a legal attack. In the attempt to reduce the modest amount of labor required by the successful Scottish retorts, many mechanical monstrosities have been evolved whose operation would require a gang of mechanics and a heap of repair parts. Others exhibit the utmost ignorance not alone of distillation methods, but of furnace design and the principles of combustion and chemistry. It would seem that some company organized primarily to get shale oil would be well advised to erect Scottish retorts and adapt them to local conditions. These well-tried furnaces are mechanically good —they operate on recovered gas with a minimum of labor, make a good yield of satisfactory crude oil with an increasing amount of paraffine, and permit the recovery of large amounts of ammonium sulphate. Should labor-saving devices be considered essential, the modern by-product coke oven with its marvellous mechanical equipment could be taken as a model, and so modified as to produce the regular temperature cycle needed for maximum yield.

As a matter of fact, on Dec. 1, 1918, of all the proposed processes and organized companies, not one was producing crude oil. In addition to this fact, there are but two or three plants ready to operate on a commercial scale—that is to say, for more than small-scale experimentation. One may understand how much of the shale agitation is merely words when it is doubtful if more than twenty barrels of crude have been produced to date from Western shale!

Construction at Elko and Watson

Perhaps the most promising attempt now under way is that financed by the Southern Pacific railroad at Elko, Nevada, where this company is erecting a Henderson retort (Scottish) for distilling shale. The Bureau of Mines is co-operating with this effort and has detailed David T. Day to act as consulting chemist. With adequate financial support and technical supervision, this attempt to adapt successful foreign practice to a local deposit should produce a mass of invaluable information.

In the Uintah basin, at Watson, Utah, the end of a 60-mile narrow-gage railroad running northwest from Mack, Colorado, the Ute Oil Co. is planning to install a 400-ton plant on the so-called "Wallace process." The bulk of the material for this plant is now on the ground, but actual construction has not yet started. The Wallace process is discontinuous and uses a vertical retort, heated from the outside. Vaporized hydrocarbons are to be withdrawn through a perforated tube extending axially down the retort. It is stated that the heating period is to be 55 minutes, which is approximately 5 per cent of the time used in passing the charge through the Scottish furnaces. It is also doubtful whether the mechanical contrivances proposed for charging and discharging will sufficiently counteract the inherent disadvantages of intermittent operation.

Activity at DeBeque

DeBeque, in western Colorado on the Denver and Rio Grande Railway, may be regarded as the center of the oil shale boom. At or near here are the sites of three plants, at each of which some work has been done. The American Shale Refinery Co. is putting up a so-called "Wingett retort," which is somewhat similar to a tall Wedge roaster. It is understood that the shale will be crushed to 10 mesh, and that the rabble arms will travel at about 30 rotations per minute! The inventor thinks he can charge 100 tons of shale per day, but as yet has no information as to whether the retort will deliver crude oil, or merely dust.

DeBeque is the scene of operations of the Mt. Logan Oil Co., which has three 20-ton units of the Galloupe process on the ground, but not yet installed. This is a long, inclined retort of crescent cross section so set that the heating gases play upon the cylindrical bottom, and contains a stirring arm manually oscillated. Volatiles are removed from the outer edges.

Two small modified Henderson retorts were erected near DeBeque about a year ago by the Oil Shale Mining Co. One of these was operated for a short while at the time of completion, and the other given short trials recently, but not much oil was made in either attempt. This company has six 6-ton units on the ground, but is not producing any oil at the present time.

Products of Distillation

Thus it appears that little of the energy so far devoted to this subject has carried the enthusiasts to the producing stage. Indeed, little is known of the substances which will be produced upon retorting. Evidently the assumption has been generally made that the products will be somewhat analogous to those of the Scottish industry. Here sufficient permanent gas is evolved to operate the process, and the crude oil is successfully fractionated and marketed as naphtha, lamp oil, gas oil, lubricating oils and paraffines by processes very similar to those in use in petroleum refineries. On the other hand, what little work has been published on Western shales show that the products of retorting are quite different from the ordinary oils of commerce. Thus, Morrell and Egloff in Chemical & Metallurgical Engineering, Vol. 19, p. 90, (July 15, 1918), and Dr. W. D. Bonner, working independently at the University of Utah, have all shown that the oils are full of highly unsaturated compounds, that they contain considerable nitrogen and sulphur and that the ordinary method of fractionating followed by acid-soda treatment does not produce stable oils of correct color, odor, specific gravity and volatility to be readily absorbed by the American market except at the expense of prohibi-

tive treatment losses. Predictions that the oil shales would produce billions of barrels of gasoline are not founded on correct premises, for the percentage of low-volatile compounds are less than assumed, and this fraction is not a distillate suitable for internal-combustion engines, since it contains its share of the complex compounds contained in the crude. Even the amount of recoverable nitrogen is so small as to reduce seriously the income from this source. Thus, the shale banks so far tested contain on the average not more than 0.6 to 0.7 per cent nitrogen. Suppose half of this is recoverable as ammonium sulphate, which would be most excellent practice from a retorter's standpoint, the shale would yield 25 or 30 pounds per ton under most favorable conditions—markedly less than that of Scottish practice. As a matter of fact the best ammonia recovery had in Dr. Bonner's work amounted to but 10 per cent of the nitrogen contents.

These statements should not be interpreted as meaning that our immense deposits of oil shale cannot be counted upon eventually to supplement the petroleum production. It cannot be too strongly urged, however, that the successful exploitation of these reserves will require the most painstaking and persistent research on the part of a competent technical and selling staff—either a retorting process must be discovered which will produce good yields of normal crude, or easy methods perfected to separate the unstable compounds, uses discovered for them, and the market educated to absorb them. Evidently this development is impossible as long as the promotor remains the prominent feature of the situation!

Treatment of Asphaltic Sandstone

A sharp distinction should be drawn between the preceding discussion of oil shales and the following information on asphaltic sandstones. As already stated, these so-called "oil sands" occur in thick and extensive deposits at many scattered localities throughout the Rocky Mountains. They consist of beds of fine, rounded sand, cemented with a heavy asphaltic oil; their nature suggests that they represent the remains of a petroleum deposit which has been so exposed that the lighter oils have evaporated, leaving the heavier residue behind.

That the kerogen in asphaltic sandstone is essentially different from that in oil shale is evidenced by the fact that it can be easily leached from the sandy aggregate by gasoline and other organic solvents. This has been done in a continuous manner at the University of Utah. A traveling belt operating in a closed leaching tank elevated the sandy residue above the surface of the digesting liquid, there to be sprayed first with solvent decanted from the sump, and later by clear gasoline recovered from the stripping still and discharge trap. The well known system of continuous counter-current decantation perfected for cyaniding and applied to numerous chemical and metallurgical leaching processes comes to mind as being quite applicable for this extraction. Covered agitators and thickeners would be used—in fact the whole system would be gas-tight in order to prevent the volatilization of the solvent, while the final sludge would pass through a filter and drier to recover the last of the gasoline or other leaching medium. The rich solutions thus formed may be separated from the solvent in a stripping still. The liquid residue is a heavy viscous oil, which is about 10 deg. Baume gravity yielding little material under 200 deg. C. when distilled. As far as studied, it appears to be quite similar to the heavy parts of Mexican and Californian petroleum, and will yield gasoline by cracking, lubricating oils, road tars and coke of marketable quality and by ordinary refining methods.

Large scale experimentation on distilling this asphaltic sandstone is to be undertaken at Casmalia, California, a point on the Southern Pacific railroad near Santa Maria, where a so-called "Day-Reed" plant is being built. The furnace consists of three tubular retorts, egg-shaped in cross section, set one above another between headers, and the whole mounted in a rectangular furnace. The retorts themselves are about 20 feet long by 15 inches high. The broken standstone enters one end of the top retort and is worked slowly to the other end by a screw conveyor; it falls through the header into the second retort, and is worked back and forth through the remaining retorts in a similar manner. Suitable exits for gas, light and heavy oils are provided.

Power at Pittsburgh

AT THE last local meeting of the American Electrochemical Society at Pittsburgh, the program was opened by a fine paper from Dr. J. F. Schrader of the Westinghouse Research Laboratory, who described the latest devices for the "Production and Measurement of High Vacua." The paper was illustrated by slides.

This was followed by an informal symposium on the electric and electrochemical interests of the Pittsburgh region. In the course of this some interesting notes by Carl G. Schluederberg, the well known "live wire" of the Westinghouse Electric & Manufacturing Co., brought out the fact that the Niagara power costs may possibly be reached in the Pittsburgh region before long. It used to be said that there would never be any such power supply at Pittsburgh to equal, say, 500,000 hp. But the statement was made that some large interests are planning now for huge plants, both coal at the mine and water power, which will give a total of nearly 700,000 kilowatts. The statement was also made that the cost of this power would, when normal conditions arrive, presumably be as low as that of power anywhere in this country.

This symposium was only the prelude to an interesting series of papers of the general electric outlook in the Pittsburgh region which it is planned to bring out before the Pittsburgh Section this winter. Interest in the local Section and its work is growing, through the energetic work of the chairman for the last year, Mr. R. E. Zimmerman of the Research Laboratory of the American Sheet & Tin Plate Co. at Pittsburgh.

Pro Patria, Pro Meter, Pro Liter

In the announcement put forth by the American Metric Association a new slogan has been adopted which reads "Pro Patria, pro meter, pro liter!" We favor the idea. At the same time we wonder whether the phrase is entirely happy. In most of us our school-boy Latin has so degenerated that we are apt to read a false meaning into the simplest expressions in the language. For instance the new slogan may unhappily be translated, "For Father, for Mother, and for a Long Drink."

Mercury Production at Almaden, Spain

Statement of Marketing Conditions—Contract with Rothschild of London and the Method by Which the Price Is Controlled—Ore Sorting and Sampling—Bustamente and Cermak Furnaces—Condensers—Production and Costs

By Dr. ROLAND STERNER-RAINER[1]

COMPARISON of production statistics, shown in Fig. 1, the world over shows that Europe has regained the lead since the peak of California's production, which occurred in the '70s of the last century. It also seems that Europe will increase its lead. Three European states at present produce a considerable part of the world's output. In the past year Spain led the production with 1500 metric tons;[2] then follows Italy with nearly 1000 metric tons, and then Austria-Hungary with nearly 850 metric tons. Besides the three largest quicksilver mines in the world—Almaden, Monte Amiata and Idria, which give the above-mentioned countries the lead in production—there are in Europe a number of smaller mines which produce notable amounts of quicksilver, either directly or as a by-product. Since, in general, there is little of interest in the method of ore dressing and reduction employed by these small plants, this section will concern itself mainly with the first of the large plants mentioned.

Environs of Almaden

The mining town of Almaden lies in the Spanish province of New Castle, near the boundary of Estremadura, and is somewhat off the road of travel—as most mining towns are. The railroad connecting Madrid with Portugal, via the Spanish border town of Bajodoz, passes through the village of Almadenejos, in the province of Ciudad-Real. The railroad station is called Chillon, and from here the city is reached over a stony road about 10 km. long. Almaden lies on the north slope of the Sierra Morena, in the highlands of central Castile, about 700 m. above sea level; the surrounding country is unproductive pasture land crossed by rocky escarpments. The whitewashed, one-story houses of the 8000 inhabitants lie mostly along one long, cobblestone road which runs along the ridge of a low hill which rises toward the west and reaches its highest elevation at the end of the city, where an old Moorish fort rests upon the crown of the hill. Most of the shafts are found a little farther on, and at the foot of the hill is the metallurgical plant, which is connected with the mines by an incline, the so-called "Plano-Automotor."

Of the earliest history of the plant no more is known than is recorded in the book of the engineer Cyarzabal, of which only one copy exists, in possession of the management. Little has been published about the ore occurrence, mining methods, metallurgy and production other than that found in various text books.

The ore bodies of Almaden, which extend under the city, are found only in the Silurian, which consists of clay slates, interbedded limestones and quartzites, which latter pass into micaceous sandstones. Three of these quartzites, having an average thickness of 8 to 14 meters, are impregnated with cinnabar. They merge gradually into the barren quartzites, but have a sharp contact with the slates. These ore bodies have become richer in depth, whereas several others in the neighborhood, as at Almadenejos and in the Val de Azogues, where La Concepcion is the oldest of the now abandoned quicksilver mines of the district, became impoverished in depth. Besides cinnabar, small quantities of "azogue virgin," or metallic quicksilver, are found. Pyrite is also present, as are traces of selenium and arsenic. Gangue minerals are almost entirely absent and are confined to a little heavy spar, dolomite and small vugs of bituminous matter.

The main ore body has an average assay value of 14 to 15 per cent mercury, while the two northerly ore bodies, which are not as large, carry lower-grade ore in part, the content of which may be as low as 2.5 per cent mercury. The average content of the ore treated during the last years has remained fairly constant and equals 11 per cent mercury;[3] the width of the ore zones is greater, if anything, than in past years. The production, however, has not been increased, even though the ore at present developed assures a forty-year life of the property with an annual production of 1000 metric tons of quicksilver. With this reserve the production could, of course, be increased to any desired figure.

Method of Controlling Price

The production has not been increased, because overproduction might so lower the price that the advantages of increased production would be nullified. Even though the Spanish Government is bound by contract to sell the entire quicksilver production through the House of Rothschild in London, enabling the latter to regulate the price by controlling the amount of quicksilver placed on the market, other quicksilver-producing countries, due to their production, are powerful enough to prevent a quicksilver monopoly on the part of Rothschild.

The contract of the Spanish Government, the sole

[1] A portion of an article published in "Osterreichische Zeitschrift für Berg- und Hüttenwesen, Vol. 62, 1914, p. 529. Translated by C. N. Schuette in connection with a coöperative investigation of the metallurgy of mercury being carried on by the United States Bureau of Mines, and the New Idria Quicksilver Mining Co., and published by their courtesy.

[2] 1 metric ton = 1000 kg. = 2204.6 lb.

[3] (Translator's note.) The quantity of ore treated, presumably in the year 1912, is given later as 16,600 metric tons. The quicksilver production for this period is 35,400 flasks, corresponding to 2.13 flasks (34.5 kg.) per ton, or a yield of 7.35 per cent of the weight of the ore treated. The discrepancy between this and the average content of the ore as here stated is probably due partly to loss in treatment, which is known to be large, and partly to errors in sampling. It is generally believed by quicksilver operators that samples, as usually taken, give results indicating a higher grade of ore than actually occurs.

owner of the mines, with Rothschild was closed as a result of a public competitive submission of proposals. The contract dates from Jan. 1, 1912, and is effective for ten years. Of the total amount of quicksilver produced by the mines of Almaden, 500 flasks are reserved to the national industries of Spain. All else is included in the contract. The contractor binds himself to sell, in London, the greatest possible quantity of mercury, which he takes over f.o.b. reduction plant at a price of more than seven pounds (libres) per flask. In return for the observance of this obligation, he receives: 1. A commission of 1.25 per cent of the net value of the sales. 2. Six shillings (chelines) for each flask that he transports to London. 3. Ten per cent of the sales price above £8:2 on any sales made above this figure.

Ore Sorting and Sampling

In order to prepare the run-of-mine ore for future treatment (a "preparacion mecanica," or ore-dressing plant, has been planned but not erected) it is transported to a large sorting floor in ox-carts; here the ore is roughly sorted by hand. High-grade ore, distinguishable by its bright color, is put aside, as is the lower-grade ore and the very low-grade wall-rock. Barren rock, bricks and wood refuse is picked out. From the remainder of the ore the larger pieces are separated with iron rakes. This ore is then screened on screens having a 5-cm. opening, thus separating the coarse and fine. After the largest pieces of the two classes of higher-grade ore and a part of the very low-grade ore have been hand-cobbed to fist size, the following grades may be distinguished:

Class I. "Metal," contains about 22 per cent Hg
Class II. "China," contains about 9 per cent Hg
Class III. "Solera," contains about 3 per cent Hg

and finally the fine ore, a mixture of the comminuted material of all classes called "vasisco," with a content of about 5 to 7 per cent mercury. During the last year 16,600 metric tons of ore were treated at the plant, of which about 13 per cent was classed as "metal," 38 per cent as "china," 34 per cent as "solera" and 15 per cent as "vasisco."

The ore is sampled in the carts and cars which transport it to the furnaces. The assay sample is mixed with hammerscales and red lead in a porcelain crucible having a gold-leaf cover and heated for three minutes. The sampling and assaying are very carelessly done. Complete analyses of the ore are not available, as the assay office is not equipped for exact work and lacks a competent analyst.

Operation of Bustamente Furnaces

By far the greater part of the ore is treated in eleven twin furnaces, "hornos Bustamente" or "hornos de aludeles" (Fig. 2). Since all of the larger metallurgical plants have long since replaced this wasteful apparatus with modern installations, Almaden is one of the few localities in Europe where this historic furnace (invented by the Peruvian Dr. Don Lopez Saaverda-Barba in 1633 at Huancavelica and introduced into Almaden by Don Alfonso Bustamente in 1646) is extensively operated. The furnace erected at that time (1646) is still in operation, while the last one was erected in 1882. Construction of this shaft furnace is too well known from the text books[1] to warrant comment here.

When the furnace operation is to be resumed it becomes necessary to draw the still warm furnace tailings, which carry about 0.012 per cent. The furnace tails are carried to the dump, which in the course of time has become tremendous, in saddle baskets on mule back. First, the larger pieces of "solera" are introduced into the shaft, the object being to prevent fine ore from falling through the convex brick grate. On this is placed "china," then "metal" and finally briquets of soot and "vasisco." On top of the ore several pans of fresh soot are placed supported by a sheet metal frame. The lump ore is charged through the side doors as far as possible, the rest being dropped through the top charge door. When both openings are closed the furnace is fired, and the ores burned for two days. After the fire has been drawn, the side and charge doors are opened to allow the cold air to enter the furnace shaft and cool the tailings.

Then the "levante," or clean-up, is started. The connections between the ascending and descending condenser branches are severed and the "aludels," also called "canos," which lead from the furnace, are taken out and placed on the aludel floor, where the quicksilver flows out and the greater part of the soot is collected.

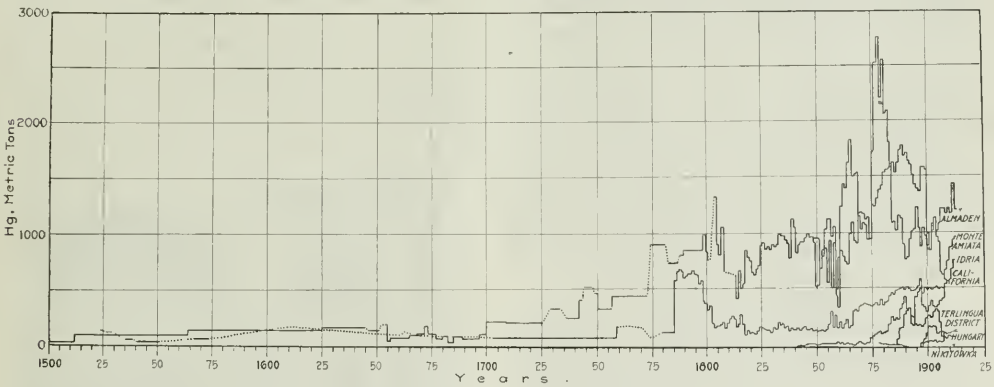

FIG. 1. WORLD'S PRODUCTION OF MERCURY FROM 1500 TO 1912

[1] Schnabel, C., Handbook of Metallurgy, Vol. 2, p. 348.

The emptied aludels, which resemble porous clay pots without a bottom, are set on the clean floor, the latter being swept from the furnaces down to the central gutter when the aludels are replaced immediately. Broken aludels are replaced by new ones of local manufacture which cost 30 centimos, and the old ones are burned in the next furnace charge. The joints between aludels are luted with a ferruginous red clay found in the neighborhood, and the furnace is ready for the next charge. The free quicksilver runs off through a floor drain into a pot below, from which an iron pipe con-

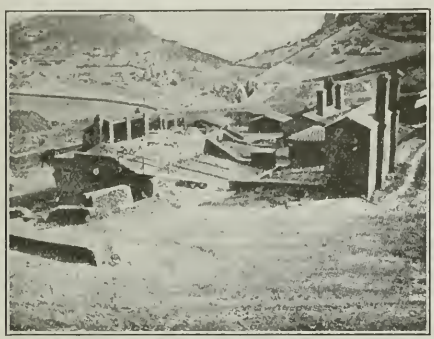

FIG. 2. BUSTAMENTE FURNACE AT ALMADEN

ducts it to the storehouse. The high-grade soot is hoed with perforated hoes until most of the trapped quicksilver has been extracted, and then is carried in woven hand baskets, called "espuertas" or "capassos," to a room at the side of the condensation chamber, where it is further treated. A considerable amount of quicksilver is scattered by all this handling. One finds puddles of mercury on all these furnaces and in their vicinity, to say nothing of the fact that the masonry and the ground are impregnated with visible droplets.

Estimation of Losses

No determinations of losses have been made, and not even estimates of probable losses are at hand. The sampling as practiced does not give reliable information as to the furnace input. It may be taken for granted that the diffusion of mercury fumes is enormous, considering the large surface presented by the lines of aludels. A considerable volume of the furnace gas escapes through the small hole in the bottom of each aludel, which is designed to afford a means of escape for the condensed quicksilver. The luting of the aludels is not so perfect as to prevent a light blue haze from hanging over them. Many of the aludels are covered with droplets of mercury on the outside, a sign that the metal was condensed when escaping. Further condensation in the fume chamber, which is divided only into two parts, is not capable of completely separating all the mercury which passes the aludel strings. The operation of the plant is discontinued during the first days of May, to be resumed during the cool days of autumn, as the hot sun practically prevents the condensation of mercury in the aludels. At that, the losses during the winter months must be very high, which is significant when the high grade of the ore and the amount of mercury produced is considered. Officially, losses are given as 3 per cent, which would amount to 36,000 kg. of mercury semi-annually, but considering all factors, it would probably be more nearly correct to place the loss at four or five times that figure.

The charge of a twin furnace consisted of 5400 kg. "metal," 9960 kg. "china," 2800 kg. "solera," 800 kg. of briquetted soot and "vasisco" and a part of the soot of the previous run. From this charge 2140 kg. of metallic mercury were recovered with a fuel consumption of 18 metric centners[5] of coal. Occasionally coke fuel is used, of which only 12 q. are used, since the preliminary heating is done by 1 metric centner of wood and 2 metric centners of coal. Two firemen control the operation. One foreman, 2 bosses, 6 men to charge the furnace and 2 to lute the aludels are necessary for a clean-up.

Cermak Furnaces and Condensers

Cyarzabal, when manager of the plant, introduced a Livermore furnace in order to increase the capacity of the plant for treating fines. This furnace was in operation until the year 1903, when it was replaced by three fine-ore furnaces of the Cermak-Spirek system[6].

In order to treat the low-grade coarse ore successfully, two twin-shaft furnaces of Spirek's design were erected. Both types of furnace are equipped with primitive Cermak condensers called "canos curvos y canos rectos," which are made locally of reinforced concrete (Fig. 3). The cooling of these condensers is poor because of the lack of water. They lead to a common flue from which a blower discharges the gases to the stack. This part of the plant, contained in a large new building, is situated at the highest elevation of the works, and gives the impression of being modern, even

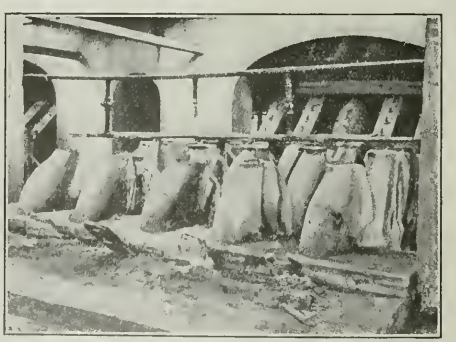

FIG. 3. CERMAK CONDENSER AT ALMADEN

though it is poorly kept up. The performance of these furnaces is considered excellent, but a thorough reform of the entire plant practice is not even thought of because the richness of the ore bodies allows any amount of waste and because laws safeguarding the health of the workingmen do not seem to exist.

The three "hornos de menudo," that is, the iron-sheathed, fine-ore furnaces, two of which have a ca-

[5] (Translator's note.) Metric centner, also called double centner = one quintal (q) = 100 kg. = 220.5 lb.

[6] Schnabel Handbook of Metallurgy, Vol. 2, p. 393. The Mineral Industry, New York, 1898 to 1902. Jahrbuch der Bergakademien, Vienna, 1900. Berichte der Weltausstellungen, Paris, 1899 to 1900. Z. f. angew. Chem., 1901 to 1905. Annales des Mines Belgique, Tom. IX, 1904. Congres international des mines, de la metallurgie, etc., Liege 25, 6, 1905. La metallurgia del mercurio VI. Congresso Internationale della chimica applicata, Rom, 1906.

pacity of 8 metric tons per 24 hours, the other 4 metric tons per 24 hours, treat 20,000 kg. "vasisco," passing a 5-cm. screen with a fuel consumption of 166 kg. of coal. The "hornos de torre," or shaft furnaces, treat 28,000 kg. "solera," with a fuel consumption of 650 kg. of coke. Eight men operate the furnaces in eight-hour shifts. The fine-ore furnaces have a special exit pipe to draw off the mercury fumes, or "vasos," from under the top row of tile, and the shaft furnaces are provided with double-charge doors. Despite these precautions the charge is never free from fume, and a halfway breathable atmosphere can only be maintained on the charge floor when the hopper is filled with a layer of "vasisco" after each charge. The ore is so rich that a continuous stream of quicksilver flows from the condensers to the storeroom. The soot is gathered into boxes during the clean-up and worked with a hoe called "rodillo." The soot-rejects are mixed with "vasisco," briquetted and burned in the Bustamente furnace, or it is added to the shaft-furnace charge. In the future it is proposed to press the soot-rejects in a cylindrical form so that they can be treated in quantity with the lump ore. The clean-ups, or "limpios," are run once a year, that is, when the "campana" is completed and repairs are undertaken; this is done in the beginning of May. These "limpios" net about 27,000 kg. of metal.

Production and Costs

The mercury stored in the storeroom is shipped in seamless Mannesmann-steel bottles which are manufactured by the Domingo de Orneta Co., at a price of 6 pesetas 10 centimos each ($1.20). Generally, old bottles that have been redeemed in London and sent back to Almaden are used. A counterbalanced sheet-iron funnel having an iron draincock serves as a weighing bucket. It is filled with 34.507 kg. of mercury[1]. This mercury is drained into the flask, which when stoppered, is ready for market.

The future production of Almaden will be on the same scale as in the past. The total production of Almaden, according to the statistics at the works, is 5,089,041 flasks. Despite these favorable conditions, the production costs at Almaden are the highest. The cost of 138 pesetas ($26.63) per ton of ore treated (figures for 1905 as given by the Revista minera, etc.) shows their production cost to be seven times as great as at Idria, where the ore is only one-tenth as rich.

Statistics of Production

According to the statistics of the Frankfurter Metallurgische Gesellschaft, the following is the production of Spain, which includes that of Asturia and other minor sources:

	Metric Tons
1900	1095
1901	754
1902	1425
1903	968
1904	1130
1905	853
1906	1567
1907	1212
1908	1068
1909	1393
1910	1114
1911	1486
1912	1490

The last figure (1490 metric tons) equals 43,800 flasks of 75 lb. (29.4 flasks of 75 lb. per metric ton).

[1]Old Spanish centner = 76 lb.

Notes on the Chemical Analysis of Red Lead

By W. F. Edwards
Studebaker Corporation, Detroit, Mich.

RED LEAD is an important industrial material of varying content of "true red lead," Pb_3O_4, and litharge, PbO, together with small per cents of metallic lead. A Navy Department specification calls for 94 per cent "true red lead," the balance to be practically pure lead monoxide, not more than 0.1 per cent of metallic lead being permissible.

Direct methods for determining the amounts of "free" lead monoxide (litharge) and metallic lead are usually not given in schemes for the analysis of red lead, and there is a variety of methods given by different authorities on paint analysis for the determination of the "true red lead."

All schemes for the analysis of red lead base the determination of the "true red lead," assumed to be $PbO, 2PbO$, on the oxidizing action of the PbO_2 part on such substances as oxalic acid, potassium iodide, ammonium ferrous sulphate, stannous chloride, etc.

The "tentative method" of the American Society for Testing Materials uses potassium iodide, following the method of Diehl as modified by Topf. By taking the usual precautions against the loss of iodine this method gives consistent results in the analysis of dry red lead.

The method briefly stated is: 1 gram of red lead is rubbed to a paste with a few drops of water and a cool mixture of 30 grams of crystallized sodium acetate, 2.4 grams of potassium iodide and 10 cc. of water and 10 cc. of 50 per cent acetic acid are added and stirred until the red lead is dissolved, when 30 cc. of water and 5 grams of sodium acetate are added. The mixture is then cooled to room temperature and titrated immediately with N/10 sodium thiosulphate.

Stock Solution Saves Time

Much time may be saved and quite as accurate analyses obtained by using a stock solution of the mixture of sodium acetate, potassium iodide and acetic acid; and also of the water and sodium acetate. The stock solution containing the potassium iodide will of course in time decompose somewhat, but the error is too small to notice unless the solution has been kept a long time in a warm place and exposed to sunlight. A blank titration run in parallel on the stock solution, or the standardization of the sodium thiosulphate on a standard sample of red lead, will insure against error. Sabin in his "Technology of Paint and Varnish" gives a formula for making up the stock solution of sodium acetate and potassium iodide with 50 per cent acetic acid.

The writer has obtained excellent results by using a stock solution made up with ammonium acetate instead of sodium acetate; 600 grams of ammonium acetate and 60 grams of potassium iodide are made up to a volume of one liter by solution in 50 per cent acetic acid. This solution can be used in large excess without giving varying results, and it can be used on red lead to which has been added litharge, lead sulphate or zinc oxide or all three together.

To try this out a series of 0.5 gram samples of a standard sample of red lead were weighed out and several

were titrated in the usual way and several more after additions of varying portions of litharge, up to ½ gram, were added; several more after varying proportions of lead sulphate, up to ½ gram, were added; and several more after varying proportions of zinc oxide, up to ½ gram, were added. The red lead was found to be the same in all cases, showing that the added substances had no effect on the per cent of "true red lead" found.

A second similar set of analyses was run using sodium acetate stock solution made up according to Sabin. These analyses showed that the added substances have no effect. However, I found the per cent of "true red lead" consistently a very little higher than was obtained by the solution made up with ammonium acetate.

It is not necessary to wait until all the red lead dissolves when using the ammonium acetate solution; ½ gram of finely divided red lead will dissolve in 25 cc. of the stock solution in less than one minute by stirring cold. It is a good plan to run in the thiosulphate solution fast enough to keep the solution a pale yellow color while the red lead is dissolving. After the ½ gram of red lead is weighed out two minutes is all the time required for making the titration. It is a speedy and satisfactory estimation for dry red lead.

It does not give satisfactory results on red lead that has been mixed with oil. It seems impossible to free the red lead entirely from the oil. In ordinary cases of separation from oil there will be enough oil adherring to the red lead so that 2N nitric acid will dissolve the red lead completely.

Analytical Equations

The analytical equations that represent the reactions for the purpose of computation are:

(1) $Pb_3O_4 + 8KI + HC_2H_3O_2 + NaC_2H_3O_2 + XH_2O = 3PbI_2 + 2I + (n—8)\ HC_2H_3O_2 + 8KC_2H_3O_2 + NaC_2H_3O_2 + (X + 4)\ H_2O$.

(2) $2I + Na_2S_2O_3 = 2NaI + Na_2S_2O_6$. 2×126.92 parts iodine are equivalent to $(3 \times 207.2) + (4 \times 16)$ parts of red lead. Therefore the iodine value of the thiosulphate used multiplied by 2.6997 (practically 2.7) gives the amount of red lead in the sample used.

In applying the iodide method to peroxide of lead to see how closely it would check I used three different samples of peroxide from a manufacturer of analyzed chemicals for reagent and made a discovery that is worth recording. The three samples were in their original bottles with the labels and lot number of the manufacturer. The labels gave the amount of certain impurities, but only one gave the PbO_2 content. One sample contained less than fifty per cent PbO_2, one a little over sixty per cent PbO_2 and the third about ninety-five per cent PbO_2. This third sample gave the per cent of PbO_2 which checked quite closely with my analysis.

Methods Used as Checks

Toch in his "Technology of Paints" gives first place to the oxalic acid and permanganate of potassium volumetric method of Lux for estimating the "true red lead." The writer has used this method in check against the potassium iodide and sodium thiosulphate volumetric method on the same sample and mixtures and has found it to check as nearly as could be expected; in fact, my checks were so close as to throw doubt on my work, the iodide method giving 95.98 per cent and the oxalic acid method giving 96.01 per cent "true red lead," the highest variation in either case being eight points in the second decimal place.

The oxalic acid method is carried out as follows: 0.5 gram red lead is brought to the boiling temperature in 30 cc. of 2N nitric acid, and 25 cc. of N/5 oxalic acid are added and again brought to a boiling temperature and titrated with N/10 or N/5 potassium permanganate solution, to determine the excess of oxalic acid solution used.

It requires a little practice to know the end of the reaction, but this once learned, it is a very satisfactory method. The solutions are all easy to make and they keep well.

This method, like the iodide method, was not capable of giving consistent results in my hands on red lead after it was mixed with oil, no matter how carefully it was extracted to remove the oil.

The writer would modify the procedure so as to use both N/10 oxalic acid and N/10 permanganate whenever a high degree of accuracy is desired.

More Analytical Equations

The analytical equations for the purpose of computation are:

(1) $Pb_3O_4 + nHNO_3 + mH_2C_2O_4 + XH_2O = 3Pb(NO_3)_2 + (n—6)\ HNO_3 + (m—1)\ H_2C_2O_4 + 2CO_2 + (X + 4)\ H_2O$.

(2) $5H_2C_2O_4 + 2KMnO_4 + nHNO_3 + XH_2O = 2KNO_3 + 2Mn(NO_3)_2 + 10CO_2 + (N—6)\ HNO_3 + (X + 8)\ H_2O$.

685.6 Pb_3O_4 equivalent to 90.01 $H_2C_2O_4$. The value of oxalic acid consumed in the solution of the Pb_3O_4 multiplied by 7.62 gives the Pb_3O_4 in the sample used.

Holly in his "Analysis of Paint and Varnish Products" obtains the peroxide content of red lead by the method of Mannhardt, which is carried out in the main as follows: 1 gram of red lead is triturated with accurately weighed 1.176 grams of crystallized ammonium ferrous sulphate, then ten grains of ammonium chloride is added and the mixture moistened with a few drops of water and the whole rubbed together after which 20 cc. water and 20 cc. concentrated hydrochloric acid are added and then all is heated on the steam plate and titrated with 3N/10 potassium bichromate solution.

The writer was not favorably impressed with the manipulations in this method and considered a 3N/10 solution too concentrated, though concordant results were obtained on samples of dry red lead.

Modification for Daily Use

The following modification of this method for use where a number of samples are to be estimated daily works out very satisfactorily, giving consistent results, and being easily carried out, the most unsatisfactory thing about it being the use of an outside indicator.

Stock solution sufficient for the day's use of N/10 ammonium ferrous sulphate is made by dissolving 39.214 grams of the sulphate in 5N ammonium chloride to make a liter of solution.

The hydrochloric acid cannot be added to this solution without precipitation of the ammonium chloride. Therefore, the hydrochloric acid must be added after the red

lead has been mixed with the stock solution. To carry out the analysis with the stock solution 0.5 grams of red lead is moistened with a few drops of water and triturated, after which 25 cc. of stock solution and 25 cc. of concentrated hydrochloric acid are added. The mixture is stirred while heated until the red lead is decomposed, when it is titrated with N/10 potassium dichromate to determine the excess of ammonium ferrous sulphate used.

The analytical equations representing these reactions for the purpose of computation are:—

(1) $2\ (NH_4)_2SO_4\ FeSO_4\ 6H_2O + n\text{HCl} + Pb_3O_4 + m\ NH_4Cl + XH_2O = Fe_2(SO_4)_3 + (NH_4)_2SO_4 + 3PbCl_2 + (n - 8)\ HCl + (M + 2)\ NH_4Cl + (X + 16)\ H_2O.$

(2) $6\ (NH_4)_2SO_4\ FeSO_4\ 6H_2O + K_2Cr_2O_7 + NH_4Cl + XH_2O = 3Fe_2(SO_4)_3 + 12\ NH_4Cl + 2KCl + Cr_2(SO_4)_3 + (N - 14)\ HCl + (X + 43)\ H_2O.$

Each cubic centimeter of the ammonium ferrous sulphate consumed in bringing the red lead into solution is equivalent to 0.03428 gram of "true red lead."

"Rapid and Accurate" Volumetric Method

In the 1910 edition of "Stillman's Engineering Chemistry" a "rapid and accurate" volumetric method of determining "true red lead" in red lead by the use of stannous chloride as the reducing agent is described as carried out by Wainwright. It is repeated in the 1916 edition, indicating that it has been found satisfactory.

N/10 iodine solution and a solution of 14.1 grams stannous chloride in water to make one liter are used. The iodine value of the stannous chloride solution is formed under conditions identical with those used in the analysis.

In the analysis one gram of red lead is moistened with water and 25 cc. of the stannous chloride and 40 cc. of concentrated hydrochloric acid are run in, and boiled until the red lead is in solution, 100 cc. cold water added and further cooled and titrated with N/10 iodine solution to determine the excess of stannous chloride used.

Only Objection Is Overcome

The only objection to this method is the boiling and cooling of the solutions, and that the value of the stannous chloride must be found under practically identical conditions of boiling and cooling with those used in the analysis.

In order to do away with this difficulty N/10 stannous chloride in N/2 hydrochloric acid was used; 0.5 gram of red lead was moistened with water and triturated until the red lead is all very finely divided (this is the condition to success), 25 cc. N/10 stannous chloride run in and stirred, then 25 cc. concentrated hydrochloric acid are added and the whole stirred until all but some white particles is dissolved and then titrated cold with N/10 iodine. The end reaction is sharp, no heating is required and the results are consistent to a high degree of accuracy.

The method also worked well on peroxide of lead, it being only necessary to double the quantities of stannous chloride solution and hydrochloric acid.

Any one of the four methods is capable of consistent and practically accurate determination of "true red lead" in commercial red lead. The writer is inclined to the use of the stannous chloride method of Wainwright, with the modifications given in this paper.

Institute of Chemical Engineers

FOLLOWING is the program as officially announced for the eleventh annual meeting of the American Institute of Chemical Engineers to be held Jan. 15 to 18, 1919, in Chicago:

Wednesday, Jan. 15

9:00 A.M.—Registration of members at Congress Hotel.

9:30 A.M.—Address of Welcome — Mr. Leonard Busby, president Chicago surface lines.
Response by President Thompson.
Business Session.

11:00 A.M.—Address of President Thompson, "Chemical Industries Made Permanent."
Symposium on Maintenance and Preservation of Our Chemical Industries: Résumé of Conditions as They Exist at Present," M. Toch; "Recommendations of the Tariff Commission in Regard to Dyes and Coal Tar Chemicals," Dr. Grinell Jones of the U. S. Tariff Commission.

12:30 P.M.—Complimentary Luncheon at Congress Hotel. The Chicago members of the Institute will entertain all visiting members and guests.

2:00 P.M.—Symposium on Maintenance and Preservation of Our Chemical Industries, continued: Addresses by the following representatives of chemical manufacturers: Dr. Louis Matos of the National Aniline & Chemical Co., Robert Hilton of the Ault & Weiborg Co., Dr. A. A. L. Veillon of the Monsanto Chemical Co., O. Dill of Perth Amboy Chemical Works.
Discussion by representatives of other chemical industries.

8:00 P.M.—Reading of Papers: "Future of the Barium Industry," Wm. H. Rollin of the Rollin Chemical Co.; "Reconstruction Aspects of Some Chemical Industries of the United States," Dr. Edward Gudeman.

9:00 P.M.—Smoker.
Members of the Chicago section of the American Chemical Society will be the guests of the evening.

Thursday, Jan. 16

9:30 A.M.—Members will leave the Congress Hotel by auto at 9:30 A.M. for the Union Depot to take a special C. & A. train to Argo, Ill., to visit the plant of the Corn Products Refining Co. Luncheon will be served at the plant and the return trip will bring members back to the Congress Hotel at about 5 P.M.

8:00 P.M.—Joint meeting with local section of the American Chemical Society. "Present Status of Nitrogen Fixation," Lieut. Col. Alfred H. White. Illustrated by lantern slides.

Friday, Jan. 17

9:30 A.M.—Business Session.

10:30 A.M.—Reading of Papers: "Reinforced Concrete Tanks for Storing Ammonia Liquors, "F. W. Frerichs; "Some Wild Engineering I Have Known," David Wesson; "Belting for Power Transmission," Ernest D. Wilson.

12:00 M. —Complimentary Luncheon.

1:30 P.M.—Excursions.
Members and their guests will proceed by autos to the plant of the Lindsay Light Co. to inspect the preparation of rare earths and the manufacture of gas mantles.
Visit to the Underwriters' Laboratories of Chicago, where special demonstrations will be made.

7:00 P.M.—Subscription Dinner at Congress Hotel.

Saturday, Jan. 18

8:00 A.M.—Standard Oil Co., Whiting, Ind.

Census of Chemical Imports

THE census of chemical imports, which for the past ten months has been under preparation for the Bureau of Foreign and Domestic Commerce, has been completed. The necessity for this census was apparent immediately subsequent to the beginning of the European war. Its need for domestic chemical manufacturers was considered by the American Chemical Society in 1915 and a committee was designated by that society to procure it. After a conference by this committee with the Chief of the Bureau of Foreign and Domestic Commerce in November, 1917, the necessary steps were taken for the promulgation of the Census of Chemical Imports, stating therein quantity and value, and percentage by quantity of all products consumed in or produced by chemical and allied industries and imported into this country during the fiscal year 1913-14.

The census was commenced in March, 1918, and during most of the time since as many as twenty-four clerks have been employed in securing these voluminous statistics. The census shows in detail every chemical and allied chemical, drug and medicine imported into this country during the fiscal year July 1, 1913, to June 30, 1914, together with the quantity, value and percentage by the country of origin of each of these articles. Incorporated in the census is detailed information concerning 2500 articles having an entered value in excess of $100, and an alphabetical list of 4000 articles having an entered value less than $100. The total import value for the fiscal year 1913-14 of all the articles enumerated in the census is in excess of $268,000,000.

The principal classes of articles included in the census are: Chemicals, drugs, medicines, coal tar products, vegetable oils, animal oils, essential oils, perfumes, perfumery materials, cosmetics, toilet preparations, paints, pigments and varnishes, dyeing and tanning materials, fertilizers and soaps. Embodied in the census is information showing the distribution according to the countries of origin of these different articles considered by classes.

The Census of Chemical Imports will be published by the Government Printing Office by Feb. 1, and will then be ready for public distribution.

Production of Lead Pigment in the U. S.

According to statistics compiled in the United States Geological Survey, Department of the Interior, the total value of lead pigments of domestic manufacture sold in the United States in 1917 amounted to $36,663,923, as compared with $31,061,589 in 1916 and $24,614,006 in 1915. The quantities marketed, however, decreased steadily, as shown in the following table:

	1917		1916		1915	
Pigment	Quantity (Short Tons)	Value	Quantity (Short Tons)	Value	Quantity (Short Tons)	Value
White lead:						
In oil...	87,331	$17,608,967	96,041	$16,560,137	122,194	$15,879,835
Dry....	27,869	4,920,864	32,938	4,714,343	33,907	3,513,856
Red lead..	25,478	5,523,018	23,035	3,933,566	19,435	2,397,900
Litharge..	44,102	8,611,074	37,739	5,853,543	26,118	2,822,415
	184,780	$36,663,923	189,753	$31,061,589	201,654	$24,614,006

The abnormal conditions created by the war manifestly reacted strongly upon the lead-pigment industry. The high cost of everything that enters into the cost of manufacturing and marketing the product is reflected in the increased value.

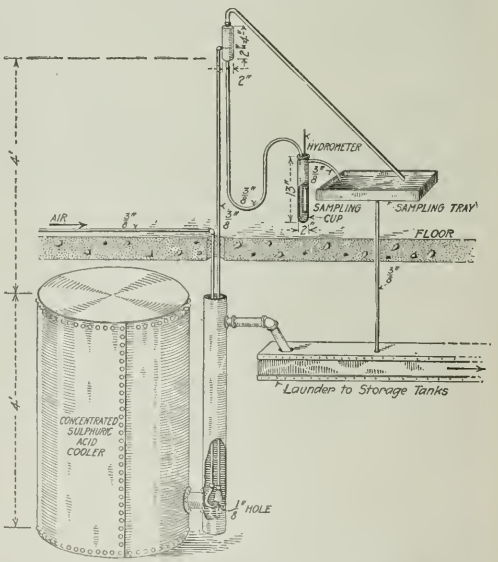
Continuous Sulphuric Acid Sampler

By S. A. Ionides

AT THE British Acetones plant in Toronto two 30-ton Chemical Construction Co. Gilchrist towers were installed to reconcentrate the sulphuric acid diluted in the regular operation there. The coolers for the concentrated acid were located between the towers below the main operating floor. Control of operation depended largely on the Baumé readings of the discharged concentrated acid, which were made each hour by dipping samples from the discharge pipe of the cooler, setting the dipper on a sampling tray and inserting a hydrometer. This operation was clumsy. Acid was apt to be splashed over the clothes of the operators, the mortality of the hydrometers was high and there was no inducement to take readings except at the regular time each hour, and with careless operating appreciable changes took place unnoticed between readings.

To remedy this situation, the simple continuous sampling device, illustrated here, was installed. It consisted essentially of a miniature air lift and as the acid was almost always below 60 deg. B., it was made entirely of lead.

The length of the upward discharge pipe from the cooler was 4 feet, and the acid had to be raised four feet further for convenient observation, which constituted a suitable ratio for an air lift. Three-eighths internal diameter lead pipe was used, that being the



CONTINUOUS SAMPLER FOR SULPHURIC ACID CONCENTRATOR

smallest size lead pipe readily available. The nozzle of the air pipe was reduced to one-eighth inch. The air pipe was connected to the air supply used for agitating the acid in the concentrators and it required only a minute flow of air to give a steady, small flow of acid up the lift and through the sampling cup. The separating head first installed allowed a little froth to come over with the air outlet, so the outlet pipe was bent

over as shown to discharge this into the sampling tray which was already installed. For the second tower the sampling head shown in the sketch was used, but the armistice was signed and the plant shut down before it was put into operation.

A slight froth formed on the surface of the sampling cup in the first installation, which at times tended to obscure the reading. To obviate this a trap was inserted between the separating head and the sampling cup in the second installation.

The important points in the construction of this apparatus were:

1. The relative diameters of the air nozzle and the riser pipe—one to three.
2. The position of the discharge pipe as near to the top of the sampling cup as possible for easy reading of the hydrometer.
3. The provision of some point at which the flow through the sampler could be observed to insure that a steady flow was passing through.

The advantages of this sampler were:

1. The ability to observe the Baumé of the discharged acid at any time.
2. The elimination of slashes of acid falling on the clothes of the operators.
3. The welcome and very marked reduction in the hydrometer casualty lists.

Patent was not applied for.

New Jersey Clay Workers Association Holds Meeting

THE fourth annual meeting of the New Jersey Clay Workers Association was held in the Queens Building, Rutgers College, New Brunswick, Dec. 17, with morning and afternoon sessions. President August Staudt, of the Perth Amboy Tile Works, Perth Amboy, presided at the morning meeting until the regular business session was concluded. New officers were elected for the ensuing year as follows: Charles Howell Cook, president Cook Pottery Co., Trenton, president; Abel Hansen, president Fords Porcelain Works, Perth Amboy, vice-president; and George H. Brown, director Department of Ceramics, Rutgers College, secretary and treasurer (re-elected). In the absence of Mr. Cook, Mr. Hansen presided for the remainder of the morning session.

Three interesting papers were presented in the forenoon, including "Some Defects in Terra Cotta," by D. F. Albery, Federal Terra Cotta Co., Woodbridge; "Sagger Mixtures," Professor George H. Brown, Rutgers College; and "The Effect of Some Fluxes in Porcelain," by F. H. Riddle, Bureau of Standards, Pittsburgh.

Professor Brown's paper covered the subject of sagger mixtures with great detail, embracing the character of sagger failures, properties of saggers, mechanical strength, hair cracks, resistance to deformation, as well as raw materials and composition. The paper was illustrated with interesting and illuminating charts.

Mr. Riddle's paper was illustrated with lantern slides, while a number of test specimens of porcelain were shown. The speaker made reference to the effect of such well-known fluxes as feldspar, magnesium oxide, calcium and barium. The clays used in the tests were from Florida, Delaware, North Carolina and Georgia; American clays exclusively were employed. The paper gave a number of interesting sidelights on the subject.

Following a recess for luncheon, the meeting reassembled, with President-elect Cook in the chair. Henry Kreisinger, Fuel Section of the United States Bureau of Mines, Pittsburgh, spoke on "Fuel Combustion"; Professor Carl B. Harrop, Department of Ceramic Engineering, Ohio State University, Columbus, gave an interesting address on "Future Kiln Developments," while a representative of the Philadelphia Textile Machinery Co., Philadelphia, spoke on the subject of "Solving One of the Clay Manufacturer's Greatest Problems," covering in detail the utility and value of the well-known Proctor drier manufactured by this company.

Professor Harrop's paper was an exhaustive study of car tunnel kilns, tracing the manufacture of different types of kilns of this style to the present time. He pointed out that the most successful tunnel kilns now in use were the American Dressler and the Didier-March, but that still much was desired in the way of greater perfection and efficiency. In tracing the employment of the tunnel kiln, he pointed out that after considerable investigation he had learned that such kilns had been developed as follows, some few in the list now having been practically forgotten:

Type	Number in Use
Anderson, 1891	1
Shaw, 1909	2
Didier-March, 1910	10
Dressler, 1915	19
Owens, 1916	11
Zwermann	1
Powell	1
Harbison-Walker	1
Total	46

This tabulation shows the extent of the use of car tunnel kilns in this country. The speaker urged greater simplicity in future kiln development, holding that there were great possibilities for the adaptation of an efficient kiln which allowed operation without the existing complications.

New Jersey Chemical Society

ON MONDAY evening, Dec. 9, 1918, the newly elected officers of the New Jersey Chemical Society assumed office. They are: President, Carleton Ellis, New Jersey Laboratories, Montclair, N. J.; vice-president, Frederic Dannerth, Consulting Chemist, Newark, N. J.; secretary, Herbert C. Cawley, the Harrison-Dupont Works, Newark, N. J.; treasurer, D. K. Howard; directors, R. P. Calvert, H. B. Baldwin, D. R. Hodgdon, W. A. Lucas, J. M. Reilly and W. G. Wright.

The scientific paper of the evening was presented by Dr. Alexander Smith of Columbia University, who spoke on "Some Common Errors in Chemical Text Books." The popular address was delivered by Mr. James M. Reilly, general secretary of the Board of Trade in Newark. He chose for his subject: "The Recent Developments of Chemical Industry in the State of New Jersey." The speaker referred to the tremendous growth of the plants which make chemicals for many different industrial processes. In this sense, the New Jersey industries are to a large extent "key industries." These include inorganic acids and alkalis, oil products, dyes and rubber-covered wire. Without them, the existence of many other general industries would be threatened. The

special guest of the evening was Lieut. J. V. Meigs, of the Edgewood Arsenal, Maryland, who spoke briefly of the production of poison gases for chemical warfare.

For Monday evening, Jan. 13, 1919, the Society has planned a "Rubber Night." An informal dinner will be held at the Achtel-Stetter Restaurant at 6 p.m. and the session will be held at the Newark Technical School at 8 p.m. New members will be admitted at that time.

The scientific paper will be by Mr. G. D. Kratz of Cuyahoga Falls, Ohio, on "The Application of the Principles of Catalysis in the Manufacture of Rubber Goods" (a study of accelerators used in vulcanization).

The popular paper will be by Dr. Frederic Dannerth of Newark, N. J., on "Some American Substitutes for Rubber." There will be an exhibit of rubber goods and substitutes for rubber in the large auditorium of the school. The Rubber Association of America will hold its annual meeting and banquet in New York City in the same week, so that a large attendance of rubber experts from other States is expected at the January meeting.

The New Jersey Chemical Society was organized with the idea of bringing together the chemists of New Jersey, co-operating with various educational activities in northern New Jersey, and of bringing the chemical profession into prominence in that part of the State, as well as the general object of promoting discussion among the chemists. The secretary will be glad to receive applications for membership. Address H. C. Cawley, secretary, E. I. du Pont de Nemours & Co., 256 Vanderpool Street, Newark, N. J.

Meeting of Manufacturers' Council of New Jersey

CHEMICAL and affiliated interests were strongly represented at the special meeting of the Manufacturers' Council of the State of New Jersey, held at the Robert Treat Hotel, Newark, on Dec. 11. This convention, called for readjustment purposes, was the first gathering of its kind held by any state organization, and brought together about 250 delegates from all parts of the state. The meeting was called to order by Warren C. King, president of the King Chemical Co. and president of the Council, at 10:30 a.m. He told of the general purposes of the meeting and the aims to be accomplished and pointed out that the primary topics before the convention were labor, cancellation of war contracts, plant readjustment, compensation insurance and factory operation on a pre-war basis. He urged a consolidation of the different manufacturing interests of the state in a spirit of co-operation to bring about utmost co-ordination and thrift for individual and collective benefit.

In this connection, he urged the establishment of a State Industrial Commission to formulate definite plans for immediate action, devising a comprehensive program for concerted effort, and at the same time place itself in position to handle such individual problems as might arise. This recommendation was approved by the delegates assembled in a resolution covering the formation of a commission to be composed of five members each from manufacturing, financial, agricultural and public utility interests, as well as five members to represent labor engaged in manufacturing and public utility work, respectively, making a total of thirty members on the committee. The personnel of the State Industrial Commission will be announced at an early date.

The subject of labor and wage scales as now operative occupied considerable discussion at the different sessions. It was pointed out that overtime must stop and the standard working day be placed into effect. Representatives of labor present at the meeting expressed full accord with these sentiments. A resolution was adopted reading, "It is the sense of this convention that there should be no radical reduction in the present scale of wages until the purchasing power of the dollar increases and in any event wages should be the last thing cut in any readjustment." Addresses on the subject of labor and wages were made by Arthur A. Quinn and Henry F. Hilfers, president and secretary, respectively, of the New Jersey State Federation of Labor.

Important addresses were made at the morning session by John D. Everett, former president New Jersey State Bankers' Association; Dr. J. G. Lipman, dean and director New Jersey Agricultural Experiment Stations, and Myrza Ali Kula Khan, Persian Minister to the United States. The afternoon was devoted to group meetings of manufacturers, banking, agricultural and labor interests, with a reassembling of the full convention for the adoption of final resolutions before the close of the day.

A banquet was given in the evening in the ballroom of the hotel, Mr. King acting as toastmaster. Among the speakers were W. H. Besler, president of the Central Railroad of New Jersey; Dr. W. H. S. Demarest, president Rutgers College, and Dr. Alexander C. Humphreys, president Stevens Institute of Technology. Col. Austen Colgate, first vice-president of the Council, who presided at the afternoon business session, was expected to address the evening gathering, but was unable to be present.

The Council has a membership of over 120 prominent concerns in the state at the present time. Among the chemical and affiliated industries now represented in the organization are: Central Dyestuff & Chemical Co., Newark; United States Metals Refining Co., Chrome; Ajax Rubber Co., Trenton; American Color Mfg. Co., Passaic; Barnes Chemical Works, Paterson; Yatman Rubber Co., Newark; United & Globe Rubber Mfg. Co., Trenton; Star Porcelain Co., Trenton; E. R. Squibb & Sons, New Brunswick, chemicals; Raritan Copper Works, Perth Amboy; Paterson Parchment Paper Co., Paterson; King Chemical Co., Bound Brook; American Oil & Supply Co., Newark; Anderson Chemical Co., Wallington; Armstrong Cork Co., Camden; J. T. Baker Chemical Co., Phillipsburg; Braender Rubber & Tire Co., Rutherford; Bulls Ferry Chemical Co., Edgewater; Columbus Crystal Co., Newark; Condensite Co. of America, Bloomfield; Charles Cooper & Co., New York, chemicals; Cumberland Glass Mfg. Co., Bridgeton; Delion Tire & Rubber Co., Trenton; Dexter Metal Mfg. Co., Camden; Didier-March Co., Perth Amboy; E. I. du Pont de Nemours & Co., Haskell; Fords Porcelain Works, Perth Amboy; Gaynor Glass Co., Salem; Howe Rubber Co., New Brunswick; R. M. Hollingshead Co., Camden, chemicals; and J. L. Mott Co., Trenton.

Personal

PROF. FRED W. ASHTON has been granted a leave of absence by the University of the Philippines and has taken over new duties as carbonization supervisor with the Chemical Warfare Service at Manila, P. I.

MR. VERNE W. AUBEL, who recently returned from blast furnace work in Australia and New Zealand, has been appointed assistant superintendent of blast furnaces at the Clairton, Pa., plant of the Carnegie Steel Co.

DR. SERGIO BAGNARA has resigned as metallurgical engineer of the Ordnance Department, U. S. A., and will locate in New York temporarily.

MR. E. H. BEDELL, who left CHEMICAL & METALLURGICAL ENGINEERING on Aug. 10 to serve in the Ordnance Department, returned on Jan. 1 to resume his former duties as Eastern Representative in the Advertising Department.

DR. GEORGE W. COGGESHALL, who has been serving with the Emergency Fleet Corporation, has resigned, and will return to his duties as a member of the staff of the Institute of Industrial Research, Washington, D. C. Dr. Coggeshall specialized during the war on concrete-ship construction, including oilproofing and waterproofing.

DR ALLERTON S. CUSHMAN has just received his honorable discharge as Lieutenant-Colonel in the Ordnance Department, U. S. A. For eighteen months he had charge of the research and chemical laboratories, including the explosives activities, at Frankford Arsenal, Pa., where he was engaged principally on ammunition and metallurgical problems. Dr. Cushman now returns to his former professional activities as head of the Institute of Industrial Research, Washington, D. C.

MR. C. T. HENDERSON has resigned as chief engineer of the Submarine Boat Corporation, Port Newark Terminal, Newark, N. J., and has accepted a similar position with the Hercules Engineering Corporation, 501 Fifth Avenue, New York. He also acts as president of the Electrolytic Engineering Corporation at the same address.

MR. ARTHUR J. HOSKIN, consulting engineer of Denver, Colo., has returned after a three-months' stay in Dillon, Mont., where he was engaged in installing an oil-shale plant.

MR. S. A. IONIDES has resigned from the British Acetones Toronto, Ltd., and intends to open up his office in Denver again as a metallurgical and chemical engineer.

MR. J. J. MCKEE, formerly New York manager of the C. A. Dunham Co. of Marshalltown, Ia., has accepted a position with the Machinery Utilities Co., 501 Fifth Avenue, New York.

MR. FRANK PURNELL, assistant to Mr. J. REPLOGLE, director of steel supply at Washington, has returned to the sales department of the Youngstown Sheet & Tube Co., Youngstown, O. Mr. Purnell was called to Washington fifteen months ago and has served in various capacities in the steel section.

MR. P. B. SADTLER, vice-president of the Swenson Evaporator Co., Chicago, Ill., who has been operated on for appendicitis, expects to return to his duties shortly after the first of the year.

MR. R. B. SAUSEN has become identified with the Star Brass Works of Chicago, Ill., and engaged in sales promotion and research work of spray cooling equipment. He was formerly district manager of the Chicago office for the Schutte & Koerting Co., of Philadelphia, Pa.

MR. HORACE V. WINCHELL has been nominated for president of the American Institute of Mining Engineers.

MR. O. WISER, for several years the assistant superintendent of the Hurley (N. M.) mill of the Chino Copper Company, has recently resigned to become president of the Republic Mining & Milling Co., with offices at Hurley and operations at Hanover. Mr. O. F. RISER is now assistant superintendent of the Chino mill.

Obituary

MR. WILLIAM GARRIGUE died of pneumonia at Toronto, Ont., Oct. 2, 1918. By his death the chemical engineering profession and the chemical industry suffered a distinct loss. Mr. Garrigue had particularly identified himself with the soap and glycerine industry and the equipment

MR. WILLIAM GARRIGUE

designed and built by his firm, William Garrigue & Co., is in use by firms throughout this line of manufacture. Mr. Garrigue was born at Copenhagen, Denmark, in 1872. He came to the United States when a child with his parents, who settled in New York City. His father, Dr. Henry J. Garrigue, was a prominent physician and writer on medical subjects. Mr. Garrigue was educated in the public schools of New York, later taking special courses at Columbia University in chemistry and studying chemistry under a private tutor in the laboratory of one of the best analytical chemists of that day in New York. After completing his education Mr. Garrigue's love of adventure and outdoor life led him to the Far West, where he soon became interested in mining. From there he went to Pittsburgh and opened a consulting and testing laboratory. About this time he became connected with the firm of W. & H. Walker, Herr's Island, Pittsburgh, who were interested in greases, oils, soaps, etc. Mr. Garrigue soon established himself as an expert in this field, which from that time on formed his sole line of activity. He acted as consulting and designing engineer for soap and glycerine equipment, maintaining offices in Detroit, Louisville, New Orleans and finally in New York and Chicago. Mr. Garrigue's principal contributions to industrial chemistry were the following: 1. The principle of double effect glycerine distillation. This was a process for distilling glycerine which has largely taken the place of the Jobbins still, previously the leading equipment. The vapor from the concentrator is used as the injected live steam for the still. This does away with using fresh superheated steam and contributes greatly to the economy of the operation. 2. Separation of trimethyleneglycol from glycerine. 3. The recovery of dynamite glycerine from cotton-seed soap stock spent lyes. 4. Reversible double effect evaporation for spent soap lye. 5. The combined evaporation of caustic soda, lye and spent soap lye in triple effect. 6. Direct autoclaving of cotton-seed soap stock before distilling fatty acids. Also decided improvements in the construction of vacuum evaporators and solvent extractors. In addition to his work in the soap and glycerine industry, Mr. Garrigue designed and built

an interesting plant for the recovery of potash from molasses distillery slop at Harvey, La., and also a complete garbage reduction plant for the city of Erie, Pa. Mr. Garrigue was a member of the American Chemical Society, the American Institute of Chemical Engineers, the Chemists' Club of New York, the New Orleans Country Club, and the Southern Yacht Club, New Orleans. His interests were by no means limited to his profession. He was one of those men who regard education as a process that should last throughout a man's life. Regardless of whether science, literature, politics or art was the subject of the conversation, he would have some idea or some new point of view to contribute that would be interesting and helpful. The feeling of loss on the part of those who knew him intimately occasioned by his sudden and unexpected death is a very real one.

Mr. William H. Stubblebine, inventor of the Stubblebine furnace, died at his home in Allentown, Pa., Dec. 6, aged 78 years. He was born in Reading, Pa., saw service in the Civil War, and on his retirement from the army in 1863 located at Bethlehem, Pa. He became one of the associates of the late John Fritz in developing the activities of the Bethlehem Iron Co., now the Bethlehem Steel Co. In 1875 he was appointed superintendent of the merchant department and in 1907 he retired. He leaves a son, W. A. Stubblebine, and two daughters.

Mr. Emerson H. Strickler, manager of the inorganic research department of the General Chemical Co., died on Nov. 22. Mr. Strickler's most recent and conspicuous achievement was the conception and development of Ryzon baking powder.

Dr. Harry Percival Corliss, until recently an Industrial Fellow in the Mellon Institute of Industrial Research, University of Pittsburgh, died at Ray, Arizona, on Nov. 16, of pneumonia following influenza, as mentioned in our Dec. 15 issue. Funeral services were held on Dec. 23 at the First Congregational Church of Wolfeboro, N. H., where his parents, Charles H. and Mary A. Corliss, are now living. He is survived by his wife, Marion Pilkey Corliss, and a sister, Mrs. Donna Nickerson. Dr. Corliss was born at Thornton, N. H., Oct. 21, 1886. He attended Brewster Academy at Wolfeboro, and was graduated in 1910 from New Hampshire State College with the degree of Bachelor of Science in Chemical Engineering. He then continued the study of chemistry at the University of Toronto, specializing in physical and organic chemistry. In July, 1912, he accepted a position as Industrial Fellow at the Mellon Institute, and in 1913 received the degree of Doctor of Philosophy from the University of Pittsburgh. Dr. Corliss' work at the Mellon Institute extended over a period of five years, during most of which time he was engaged in physical, chemical and metallurgical research. This research resulted in the development of several important improvements upon the flotation process for the recovery of minerals. Perhaps his greatest contribution to this industry was the discovery of alpha-naphthylamine as a flotation agent. It is too early as yet to estimate the full value of this discovery, but the excellent practical results already following its use warrant the belief that the work of Dr. Corliss will eventually be recognized as being of first importance in this field. In July, 1917, he accepted a position as chemical and metallurgical engineer with the Metals Recovery Co. in order to initiate the large scale application of his discoveries in the flotation mills of the Southwest. In this work he was uniformly successful and was rapidly making for himself an enviable reputation as a metallurgical engineer when death called him. From his boyhood up, Dr. Corliss' associates recognized in him the qualities of marked intellectual brilliancy and very real moral worth. All through his student days the highest scholastic honors came to him without conscious effort on his part because he loved the study of chemistry in all its branches. He brought the same qualities of mind and spirit to his research work at the Mellon Institute and to its extension in the wider fields of industrial application. His many friends will feel that by his death the world was deprived of a life which held unusual possibilities for useful work and high accomplishment.

Mr. Henry Edward Randall, Jr., died on Oct. 21, aged 25 years. His death occurred after an illness of one week at Montreal General Hospital as a result of pneumonia, following an attack of influenza. Mr. Randall was a native of Vermont, was graduated at Massachusetts Institute of Technology in 1913 and immediately accepted a position with the Shawinigan Water and Power Co. of Canada, with which company he was affiliated for five years in various branches of their system—with the North Shore Power Co. of Three Rivers, Quebec, as power sales engineer and assistant to the vice-president in Montreal, and as

HENRY EDWARD RANDALL, JR.

general manager of subsidiary companies. He possessed high ideals of serving his country in an industrial way during the war and was one of the most successful captains in the Montreal Victory Loan drive of November, 1917. On Oct. 1, 1918, Mr. Randall became general manager of the Ludlum Electric Furnace Corporation and removed to New York. He was also consulting engineer for the Canadian Ferro-Alloys Co. in Shawinigan Falls, Quebec. Mr. Randall was a member of the American Illuminating Electrical Engineering Society, American Electrochemical Society, American Foundrymen's Association, Canadian Society of Civil Engineers, Canadian Electrical Association, Engineers' Club of Montreal, Marmier Club of Canada and Phi Delta Theta Fraternity.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, Dec. 28. — Prices are declining. In general consumers are not adding to stocks, with a result that all markets are dull at present. Major transactions are expected after New Year's.

Aluminium:—The Government prices on ingots 98 to 99 per cent Al are $660 a ton f.o.b. plant in 50-ton lots; $662 down to 15-ton lots; and $666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

Antimony:—Market continues to be dull with prices as low as 7½c. per lb.

Lead:—In common with the general trend, lead is declining in price, East St. Louis being $114 per ton. Small sales are being made at 6c. per lb. in New York; 5¾c. appears to be the probable objective.

Tin:—The tin market is not under domestic control and prices are generally dull at 72½c. per lb. Minor sales at 71c. have been reported, but the U. S. Steel Products Company has purchased 10,000 tons at 72½c., so that lower prices are not probable.

Copper:—The producers have agreed on a price of $460 per ton for carload lots. Large foreign sales are predicted, as this is believed to be a permanent price.

Copper sheets, hot rolled	lb.	$0.36 —	$0.37½
Copper sheets, cold rolled	lb.	.37 —	.38½
Copper bottoms	lb.	.44 —	.45½
Copper rods	lb.	.36 —	.37
Copper wire	lb.	.29½—	
High brass wire	lb.	.28½—	.29½
High brass sheets	lb.	.28½—	.29½
High brass rods	lb.	.26½—	.28½
Low brass wire	lb.	.32½—	.34½
Low brass sheets	lb.	.32½—	.34½
Low brass rods	lb.	.33½—	.35½
Brazed brass tubing	lb.	.37 —	.39
Brazed bronze tubing	lb.	.42½—	.44½
Seamless copper tubing	lb.	.41 —	.43
Seamless bronze tubing	lb	.45 —	.46
Seamless brass tubing	lb.	.37½—	.39½
Bronze (gold) powder	lb.	1.00 —	1.75

Tungsten:—The buyers of tungsten are decidedly cautious, though there is not likely to be any unlooked-for changes. Prices are nominal, scheelite bringing $25, wolframite, $20 to $21, with no sales of low grade reported.

Zinc:—Consumers are drawing on their stocks, making a dull market. Spot New York is quoted at $166 per ton; East St. Louis, December, $160 per ton; January, $151; February, $149, and March, $148.

OTHER METALS

Bismuth	lb.	$3.50—	$3.65

Iridium	oz.	175.00—	
Palladium	oz.	135.00—	
Platinum	oz.	105.00—	108.00
Silver	oz.	1.01½—	

The Iron and Steel Market

The theory propounded in our last review, that iron and steel prices as established by Government control would be continued for an indefinite period because there was more to be gained by maintaining prices than by cutting them, has been borne out in substance though not in form Steel prices have been reduced, and for this our last review had this saving observation: "Of course there is the bare possibility of a new and lower level of prices being put out, perhaps under Steel Corporation leadership, in hope of the market being stabilized upon it, but that is extremely improbable." It was due to Judge Gary's courage and influence that what seemed extremely improbable actually occurred. As the machinery of Government price fixing had not been scrapped, the iron and steel industry had an opportunity to get together and discuss what recommendations it would make to the War Industries Board with respect to prices that might be named for the first quarter of the new year. It is stated that when the meeting opened about nine-tenths of those present were opposed to recommending that reductions be made. Through Judge Gary's leadership the meeting was led to passing, practically unanimously, a resolution empowering the general committee of the American Iron and Steel Institute to recommend price reductions. A definite schedule, it appears, had been formulated, but it was not presented at the meeting. When the committee met the War Industries Board according to an arrangement that had been made long before, there were mutual felicitations appropriate to the ending of the war, and then Judge Gary undertook to read the prepared memorandum of suggested price reductions. The chairman of the board's price fixing committee at once stated that it would not be desirable to have the suggestions read into the minutes and the meeting promptly adjourned. The statement was then given to the press.

Readjustment to a Peace-Time Basis

The object of the suggested reductions was to take a step in the direction of readjusting the iron and steel price structure to a peace-time basis, to set an example to the sellers of other commodities used in construction work so as to facilitate the resumption of construction operations and to furnish a basis for the adjustment of prices under such contracts for the sale of steel as otherwise would hardly be specified against. By making slight reductions the market would be stabilized and if the new prices were not low enough for the indefinite future declines would at any rate be postponed. The steel makers promptly adopted the suggested reductions for their part, but the blast furnaces have not adopted the suggestion of a $3 reduction in pig iron. They maintain that they are well sold up, say as to 90 per cent of their prospective make to July 1, and on contracts that can be enforced. Many steel contracts, on the other hand, are in accordance with the trade practice subject merely to the desire of the buyer to specify under them.

Unfinished steel is reduced $4 a ton to $43.50 for billets, $47 for sheet bars and small billets and $46 for slabs, rods being left at $57. Reductions in finished steel, in dollars per net ton to cents per pound are: Plates, $5 to 3c.; shapes, $4 to 2.80c.; bars, $4 to 2.70c.; blue annealed sheets 10 gage, $7 to 3.90c.; black sheets, 28 gage, $6 to 4.70c.; galvanized sheets, 28 gage, $4 to 6.05c.; steel pipe, $6 to a card with 54 per cent basing discount. Wire products are not reduced. The schedule aims to take into account production costs in the different lines. The suggested reduction in pig iron is $3, which would make basic prices, f.o.b. furnace or f.o.b. basing point in certain cases, $30 for basic, $32.20 for bessemer and $31 for No. 2 foundry, 1.75 to 2.25 per cent silicon.

Pig Iron Prices

Apart from the argument that their product is already well sold up on firm contract, the blast furnaces probably feel that reduction should be avoided at this time because a general reduction would not promise a stable market to the same extent as would exist in steel, since the pig iron market would still have some abnormal alignments to smooth out. The control prices for the different districts do not bear the relations to each other that usually obtain. Birmingham is as high as Valley, Eastern Pennsylvania has a Pittsburgh basing, and so on. These relations will not continue indefinitely.

War orders are practically all canceled by this time, and requirements on behalf of shipbuilding and the railroads are on a reduced basis, in the case of shipbuilding because there is an accumulation of steel and in the case of the railroads because the matter of control and ownership of the railroads for the future is not determined, this preventing the carrying out of any definite policy. The demand for steel that accumulated during the period of delivery control is being worked out. In the case of sheets this is quite heavy, automobile builders and various metal working shops being ready and anxious for deliveries. In other lines there is some accumulation. No new demand is originating from ultimate consumers, particularly from investors. The need may exist for more factories, bridges and the like, but it is too soon for it to be expressed. Lighter and lighter operation of the steel industry as a whole is promised until regular investment buying becomes a factor. Steel production may drop to 80, 70 or possibly even 60 per cent of capacity in from one to three months.

Safety for Steel User Demanded

The revival of demand for steel on a broad scale commensurate with the capacity of the industry hinges chiefly upon the matter of stability and cost of investments. The investor in works of permanent construction must be assured of safety for his investment—no bolshevism—and of there being no saving by postponing action. The cost of producing steel is high and may remain nearly as high as now. The cost of putting steel into employment is still more abnormal, by reason of high costs of other construction material, of high wage rates and labor scarcity and of very indifferent performance by labor. For a full demand for steel to be expressed there is more need for reduction in the cost of consuming steel than for reduction in the cost of producing steel. Thus the steel producer has not the power to make conditions favorable to heavy production and consumption of steel, but must bide his time, meanwhile endeavoring to squeeze out of the contract business on books as much tonnage as possible and at as favorable prices as possible, putting his works in good shape and weeding out the worst slackers in the working forces.

Chemical Market

HEAVY CHEMICALS:—Conditions surrounding this market have developed into an exceptionally unsettled situation. Many of the buyers were seemingly of the impression that shortly after the armistice signing immediate resumption of peace conditions would set in, but this having not taken place has apparently created a very quiet market, whereby the trading that is passing is only for pressing needs, with no disposition on the part of buyers to purchase ahead, while also great anxiety is noticeable among dealers relative to the final condition, after the readjustment takes place, and which is now under way. However, during the interval many price changes are being effected, and almost in every instance having a downward tendency. Second hands, who are apparently anticipating further reductions, are selling below the manufacturers' prices.

Caustic Soda:—There has been a continued indifferent attitude on the part of buyers, and the market during the latter part of the week developed a rather weak position, with material from the warehouses declining from $3.90 to $3.80 per hundred pounds. The trade is looking forward to the day when steamer space will be more free, and many prominent authorities have this item noted for a large volume of foreign business. Second hands are offering the product over next year at price concessions, while producers' quotations are unchanged at $3.30 to $3.40 basis 60% works.

Soda Ash:—Demand for this product has been comparatively light, although factors are also looking forward with confidence to an improved export movement, but any opinion is more or less of a speculative nature owing to the uncertainty surrounding the freight situation. Bag material in New York was offered at from 2c. to 2¼c. per pound, while light ash in barrels was available from the warehouse at $2.40 and double bags from middle western shipping points were quoted at $2.40 to $2.50 per hundred pounds.

Bleaching Powder:—Trading of a minor character continues to feature this market, but producers are apparently in a position to maintain their prices, at the recent decline. The material in domestic drums was quoted at from 2c. to 2¼c. per pound, while that in export drums was held at 3½c. to 3¾c. per pound F.A.S.

Bichromate of Soda:—No material improvement can be traced in the consuming demand for this product. Fair quantities of the material was available in the resale market at from 17c. to 17½c. per pound, while first hands were quoting at from 17½c. to 18c. for goods from the warehouses.

Bichromate of Potash:—Trading in any appreciable quantity is not in evidence; however, stocks on the spot are adequate for the current call. Dealers continue to quote at from 38c. to 40c., according to quantity.

Hyposulphite of Soda:—The precipitated product, which is the most preferable, is none too free in supply, although consuming requirements are not strong and the situation on the whole is well met. Offerings of the product are made at 3½c. per pound, but some business has passed below this figure.

Bicarbonate of Soda:—Producers report a fairly active call for this material on contract, but the recent activity in the market for spot goods has eased up to a very noticeable extent, due to the fact that certain buyers who were taking considerable of the material from the market have bought up to their requirements. Barrel material is quoted at 3¼c. per pound, while that in kegs is held at 3½c. per pound.

Permanganate of Potash:—Second hands are keeping spot prices for this commodity rather unsettled, while first hands are reporting a rather steady market at $1.50 for the U.S.P. product. The technical grade is subject to no important call and is quoted at from $1.25 to $1.30.

Carbonate of Magnesia:—The market remains quietly firm, with no price changes noted, and trading is of a routine nature, with no interest otherwise noted. Standard brands in bags are offered at 12½c. to 14c. per pound, while the product in barrels is quoted at 16c. to 18c. per pound.

COAL TAR PRODUCTS:—The quietness that has been in evidence for some time continues and has had its effect on the market, with many of the items subject to a decline. Buyers are apparently of the opinion that further reductions in prices will develop, and purchasing is merely for immediate needs. This condition, in addition to the shading of prices, featured the market during the interval. Among the crudes, benzol prices were firmly maintained by the producers, while phenol has been subject to a sharp decline, with frequent cheap offerings appearing in the resale market. Toluol, which is now in liberal supply on the spot, has also gone down with a swoop. There are many of the intermediates which are still in scant supply, but owing to the seasonal dullness the situation on the whole is well met.

Benzol:—Prices for this commodity are firmly maintained despite the quietness that is prevailing, with no indication of any material changes developing at the moment. The present demand is of a routine nature, with no other interest noted.

Phenol:—An unsettled condition has developed in this market due to the extensive stocks reported to be on hand in the various directions, and producers have reduced their prices 10c., while offerings in the resale market are frequently heard at from 5c. to 10c. below this figure.

Metatoluolenediamine:—The commodity is another of the items that has been affected through the recent decline in toluol and factors in this line are now offering at from 10c. to 15c. below the recent quotations, with very little interest shown on the part of buyers, who seemingly are anticipating a further decline.

Diethylaniline:—The slack that has also appeared in this market has brought about an easier situation so far as stocks are concerned and prices in some instances have declined from 25c. to 50c., while other directions are not disposed to alter their recent quotations.

Benzidine:—Local interest in the product is without special feature and the sulphate seems to be entirely neglected, while the only interest noted at the moment is for the base product for export purposes. Stocks on the whole are in sufficient quantities to take care of additional business, but prices are quotably unchanged.

Aniline Salt:—This item of the coal tar products has been subject to no important call during the past two weeks, with anxious weak holders playing havoc with the market on several occasions. Producers, however, have not changed their quotations since the recent decline.

Benzoic Acid:—Under liberal offerings and the continued quiet demand the market has apparently developed a rather weak position and the trading that is passing is transacted at some low levels, although producers have not materially changed their prices.

Alpha Naphthol:—The market remains quietly firm, with the demand for consumers' use being of a routine nature and prices for both the refined and crude grades being firmly maintained by producers.

Metaphenylenediamine:—The item is neither in pronounced supply nor demand and prices are fairly steady.

Metanitraniline:—Stocks of this product are adequate for the current call and dealers in the material are experiencing no difficulty in maintaining the present prices.

Dimethylaniline:—The consuming demand has eased up to a very noticeable extent and stocks therefore have accumulated, with the result that in some quarters price concessions were made, but this situation has originated no activity on the part of buyers.

Dinitrophenol:—There are now ample supplies on the spot of this product, which has been in scant supply for a long period, but quoted prices are subject to no material change.

Metanitroparatoluidin:—No important stocks of this product are noted and the spot situation is more or less nominal, with prices remaining firm.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET DEC. 27, 1918

Acetic anhydride	lb.	1.60 —	1.85
Acetone	lb.	.25½ —	.25½

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

ANNISTON—The Woodstock Iron & Steel Corporation will rebuild its sintering plant used for desulphurizing iron ores, recently destroyed by fire entailing a loss of $100,000.

Arizona

KINGMAN—The Catherine Mines will rebuild its mill at Pyramid, near here, and plans to renew operations on a larger scale.

MAYER—The Arizona Binghampton Copper Co. recently increased its capital stock to provide for extensions. Plans include the construction of a new addition to its flotation mill and the sinking of a new three-compartment shaft 1200 ft. It is understood that the company is planning for the erection of an aerial tram to the Humboldt smelter, about five miles.

WINKLEMAN—The Lavelle Gold Mining Co. will build a mill building, a 12 x 15 ft. dodge crusher, 50-ton Quenner dry crusher, amalgamation plates, four Wilfley tables and is in the market for crushers, plates, tables and accessories for second unit which will be built in July, 1919. Estimated cost, $60,000. A. Parker, 315 North 2nd St., Phoenix, superintendent.

California

CORONA—D. C. Crookshank, 322 East Holt St., will soon receive bids for the construction of a two-story, 80 x 88 ft. acid house for the Exchange By-Products Co., Corona. R. H. Orr, 1251 Van Nuys Bldg., Los Angeles, architect.

CORONA—The Exchange By-Products Co. has awarded the contract for the construction of a two-story, 80 x 88 ft. acid house, to the Oresmer Manufacturing Co., Riverside. Estimated cost, $30,000.

LOS ANGELES—The Western Pipe & Steel Co., North Broadway, has acquired a tract consisting of 130 lots in the Hay District, Vernon, near here, and will build extensions for the manufacture of riveted steel, iron and steel pipe, oil well castings, tanks, etc.

Colorado

CRIPPLE CREEK—The Lincoln Mines & Reduction Co. will build a new concentration plant at its manganese properties.

DURANGO—Bulkeley Wells and associates will build a new mill having a daily capacity of 200 tons in connection with the development of large alunite-potash deposits on Calico Peak.

PITKIN—The Pennsylvania Molybdenum Mines Co. will build a new mill at its Bon Ton mine.

Connecticut

NEW LONDON—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a laboratory building, to T. A. Cassidy, Fitchburg, Mass. Estimated cost, $17,800.

Delaware

NEW CASTLE—The American Manganese Steel Co. will build a one story, 60 x 60 ft. addition to its core oven works. Estimated cost, $18,000.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Department, has awarded the contract for the construction of a laboratory building here, to the Boyle-Robertson Construction Co., Evans Bldg. Noted Nov. 30.

Florida

KEY WEST—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will soon award the contract for the construction of a photo-laboratory here. Estimated cost, $7000. Noted Dec. 15.

OKEELANTA — The Okeelanta Stock Farms Packing & Canning Co., 212 New Tatum Bldg., Miami, will build a dehydrating and canning plant in connection with its hog farm here.

Georgia

GRIFFIN—The Georgia Cotton Mills will enlarge its bleachery and will install kier, one set of dry cans, mangle, switcher and calender.

Idaho

KELLOGG—The Mullan Milling Co. will install fine crushing and flotation machinery and equipment in the new 150-ton mill recently completed.

WALLACE—The Spokane Metals Recovery Co., operating at Nine Mile, near here, will rebuild its plant recently destroyed by fire, entailing a loss of over $22,000. Plans include the installation of a ball mine and other equipment.

Illinois

CHICAGO—John F. Jelke Co., 759 South Washtenaw Ave., will build an addition to its butterine factory.

CHICAGO—R. J. Kittredge & Co., 812 Sulphur St., has purchased a site on West 47th St., and Whipple Ave., and will build a large plant for the manufacture of labels and wrappers. The first unit is estimated to cost $200,000.

CHICAGO—Wilson & Co., 41st St. and Ashland Ave., has awarded the contract for the construction of a 3 story, 20 x 34 ft. fertilizer, dryer and storage building, to J. B. Mullen, 1128 South Michigan Ave. Estimated cost, $65,000. Noted Oct. 15.

MAYWOOD—The Sanitary District, 900 South Michigan Ave., Chicago, will build a one and two story treating plant, to include drying plant, pumping station, etc. Total estimated cost, $800,000. E. L. Barrett, 900 South Michigan Ave., Chicago, architect.

Indiana

HARTFORD CITY—The Ft. Wayne Corrugated Paper Co., Murray and Barr St., Ft. Wayne, will build a two story addition to its factory here. D. S. Griffith, owner.

Iowa

CLARINDA—The city has had plans prepared for the construction of a mechanical filtration plant to purify the water obtained from the Nodaway River.

KEOKUK—The Gas Tank Recharging Co. will build a plant here for the manufacture of calcium carbide. Estimated cost, $500,000.

Kentucky

MARION—John Summers and associates will install a jig mill on a mining tract here and is in the market for equipment for same.

PADUCAH—The Union Mining Co., recently incorporated with a capital of $25,000, will develop about 140 acres of fluorspar and lead properties in the Paducah Section. Plans include the installation of new lead mining and fluorspar machinery. B. F. Weatzel, Shawnee Parkway and Chestnut St., Louisville, president.

Maryland

BALTIMORE—The Baugh Chemical Co., foot Clinton St., has awarded the contract for rebuilding its nitrate ovens, to C. L. Stockhausen, Marine Bank Building. Estimated cost, $20,000.

ELKTON—The Scott Fertilizer Co. will rebuild its plant recently destroyed by fire entailing a loss of $250,000.

SPARROW'S POINT—The Bethlehem Steel Co. has awarded the contract for the construction of a one story, 73 x 1070 ft. steel plate mill, to Deverill. Spencer & Co., 514 Garrett Building, Baltimore. Estimated cost between $150,000 and $200,000.

Massachusetts

BOSTON—The Air Reduction Co., 120 Broadway, New York City, N. Y., has awarded the contract for the construction of five buildings of the modified Austin No. 1 type, to the Austin Co., 16112 Euclid Ave., Cleveland, Ohio. Estimated cost, $40,000.

BOSTON—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will build a galvanizing plant here. Estimated cost, $50,000. C. W. Parks, chief.

CAMBRIDGE—Lever Bros. Co., 176 Broadway, has awarded the contract for the construction of a 5-story, 75 x 170 ft. addition to its factory for the manufacture of soap and glycerine, to Stone & Webster, 147 Milk St., Boston. Estimated cost, $500,000.

Michigan

DETROIT—Frederick Stearns & Co., Jefferson Ave., will build an eight story, 100 x 110 ft. drug manufacturing plant. Albert Kahn, Marquette Building, architect, preparing plans.

DETROIT—The Michigan Smelting & Refining Co., 1685 Joseph Campau Ave., has had plans prepared for the construction of a two story, 50 x 63 ft. cupola house, on Clay and Joseph Campau Aves. Albert Kahn, Marquette Building, architect.

PETOSKEY—The Petoskey Portland Cement Co. will build a cement plant. J. C. Buckley, 38 South Dearborn St., Chicago, Ill., engineer.

Minnesota

COLUMBIA HEIGHTS—The city will receive bids about June for the construction of a sewerage system. J. W. Shaffer, New York Life Building, Minneapolis, engineer.

ST. PAUL—O. B. Dailey & Son, 460 Selby Ave., will build a factory for the manufacture of gasoline substitute.

Missouri

ST. LOUIS—The Christian Brothers College, 5270 Page Ave., will install a chemical laboratory in the three story college which it will build on Clayton and Skinker Roads. Estimated cost, $200,000. Henry P. Hess, 4811 Cote Brilliant Ave., engineer.

ST. LOUIS—The Goodyear Metallic Rubber Shoe Co., 500 Bittner St., has awarded the contract for the construction of a two-story, 62 x 65 ft. vulcanizing building, to the Unit Construction Co., Title Guarantee Building. Estimated cost, $20,000.

ST. LOUIS—The St. Louis Hide & Tallow Co., 412 Talcott Ave., will rebuild its hide and tallow factory recently destroyed by an explosion, entailing a loss of $15,000.

New Jersey

BOUND BROOK—A. A. Marlow & Sons will build a chemical plant for the manufacture of liquid sulphur and chemicals and are in the market for sheet lead, lead pipes, boilers, compressors, sulphur burners, storage tanks and cylinders.

GLOUCESTER—The United States Government will build a fumigation plant and laundry here. Estimated cost, $26,000.

New Mexico

FT. HANCOCK—A. Kraft, operating a copper mine near here, will build a new 100-ton gravity concentrating and flotation mill at his plant.

New York

BROOKLYN—John Bene & Sons, 641 Dean St., will build a three story, 100 x 100 ft. chemical factory on Carlton Ave. near Fulton St. W. H. Gompert, 171 Madison Ave., New York City, engineer.

BUFFALO—The Buffalo Slag Co., Ellicott Square, will build a one story, 70 x 100 ft. crusher plant. Estimated cost, $12,000.

BUFFALO—W. P. Whitney, architect, 38 South Dearborn St., is preparing plans for the construction of a clay products plant in the suburbs near here. Plans include a one story, 10 x 12 x 700 ft. conveyor house; one story, 57 x 200 ft. warehouse, two small storage buildings, etc. Total estimated cost, $100,000. Owner's name withheld.

NEW YORK—F. L. Dowling, president of Manhattan Borough, has awarded the contract for furnishing and delivering liquid chlorine, to the Electro Bleach & Gas Co., 13 East 41st St., $6120; furnishing and delivering sulphate of copper, to J. Grieg, 39 Cortlandt St., $2901. Noted Dec. 15.

NIAGARA FALLS—The Acheson Graphite Co., Buffalo Ave., has awarded the contract for the construction of an addition to its plant, to the John W. Cowper Co., Fidelity Building, Buffalo. Estimated cost, $15,000.

North Carolina

MONROE—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will soon award the contract for the construction of a radio building here. Estimated cost, $250,000. Noted Dec. 15.

Ohio

AKRON—The Akron Soap Co., Cuyahoga St., will build a two story, 40 x 50 ft. disposal plant. Estimated cost, $5,000.

CANTON—The Republic Rubber Corporation, Albert St., Youngstown, will enlarge its plant here, to double its present capacity.

CLEVELAND—The Cleveland Furnace Co., 1314 Rockefeller Building, will build a one story, 52 x 62 ft. laboratory building, at 315 Clark Ave. Estimated cost, $6000. F. A. Dearborn, c/o owner, architect.

CLEVELAND—The Grasselli Chemical Co., Guardian Building, will build a one story, 82 x 204 ft. chemical plant, at 2625 Independence Rd. Estimated cost, $25,000.

CLEVELAND—The Ohio Bronze Powder Co., 1120 East 152nd St., has awarded the contract for the construction of a two story, 56 x 70 ft. factory, to the McMillan Co., 1794 East 55th St. Estimated cost, $18,000.

CLEVELAND—The United States Copper Co., Guardian Building, has awarded the contract for the construction of a brass and copper tube mill, to the Hunkin Conkey Construction Co., Century Bldg. Estimated cost, $100,000. Noted Dec. 15.

PARMA—(Cleveland P. O.)—Swift & Co., 3240 West 65th St., has awarded the contract for the construction of a two story, 50 x 75 ft. fertilizer factory, to the William Moore Co., 1278 West 4th St., Cleveland. Estimated cost, $25,000. Noted Oct. 31.

TOLEDO—The Paragon Refining Co., 2935 Front St., will improve its plant. Estimated cost, $50,000. J. C. Smith, secretary.

TOLEDO—The S. S. Royster Guano Co., Second National Bank Building, will build a sulphuric acid plant adjoining its present plant. Estimated cost, $500,000.

TOLEDO—The Standard Steel Tube Co., Fitchland Ave. and Detroit & Michigan Central R. R., has purchased a 40 acre site on South Detroit Ave., and will build a factory. Estimated cost, $500,000.

YOUNGSTOWN—The Industrial Gas & Chemical Co., recently incorporated with a capital of $250,000, will build a plant for the manufacture of welding gases, chemicals and dyestuffs.

Oklahoma

BLACKWELL—The Bartlesville Zinc Co. will enlarge its plant here.

LAWTON—The city has awarded the contract for the construction of a filtration plant, to the Selden-Breck Construction Co., Fullerton Building, St. Louis, Mo. Estimated cost, $157,000.

OKLAHOMA—The American Castor Oil Co., 600 Colcord Building, will build a tenton plant and install machinery in same. Estimated cost, $50,000. H. C. Leete, manager.

TULSA—The United States Compression Inner Tube Co., Daniels Building, will build a plant for the manufacture of rubber inner tubes for automobiles. C. R. Porter, secretary-treasurer.

Oregon

BAKER—Harry M. Quinn and C. G. Flanagan, Seattle, will install a flotation plant to replace the old 60-ton concentrator in the Highland Mine near here.

SUMMER LAKE—Jason C. Moore has leased Summer Lake from the State Land Board and will build a commercial reduction soda plant, for the manufacture of soda ash and potash, produced from the deposits of the lake. When production begins, royalty will be paid to the State Land Board at the rate of $.25 per ton for soda ash and $.50 for potash. Estimated cost, $90,000. E. W. Lazell, Railway Exchange Building, Portland, chemical engineer.

Pennsylvania

MARCUS HOOK—The National Aniline & Chemical Co. has awarded the contract for the construction of a 106 x 109 ft. modified Austin No. 9 building to the Austin Co., 16112 Euclid Ave., Cleveland, Ohio. Estimated cost, $32,000.

MT. HOLLY SPRINGS—The Mt. Holly Paper Co. has awarded the contract for the construction of a one story, 22 x 25 ft. addition to its paper factory, to H. A. Lackey, 520 North West St., Carlisle. Estimated cost, $5000.

PHILADELPHIA—The Kensington Hygeia Ice Co. has awarded the contract for the construction of a one story addition to the new cooling tower on Trenton Ave. and Huntingdon St., to the Cooling Tower Co., 15 John St., New York City, N. Y. Estimated cost, $5000.

PHILADELPHIA—The Samaritan Hospital, Ontario St., east of Broad St., will receive bids about June 1st, for the construction of a two-story, 25 x 81 ft. addition to its hospital, including a laboratory. Estimated cost, $12,000.

Rhode Island

PROVIDENCE—The Providence Steel & Iron Co., Kinsley Ave., has awarded the contract for the construction of a one-story fabricating plant, to Williams & Merchants, 87 Weybosset St. Estimated cost, $25,000.

South Dakota

HILL CITY—The American Tin & Tungsten Co. will remodel its plant near here and is in the market for a Telsmith gyratory crusher, Hardinge ball mill, Deister Plato slime table, Richards pulsator classifiers and electric furnace for smelting tin concentrates. Ralph S. Meyerin, superintendent.

Tennessee

BUTLER—The Elenor Manganese Co., recently incorporated with a capital of $15,000, will install the necessary equipment in the mine recently acquired from A. H. McQuenn to provide for an initial capacity of about 15 tons. R. B. Hayes, Masontown, Penn., president.

Texas

ABILENE—Charles Lindsey, 203 Fourth National Bank Building, Wichita, Kan., and others, have purchased a site here and will build an oil refinery. Estimated cost, $750,000.

COLLEGE STATION—The Board of Directors, Agricultural & Mechanical College of Texas, will receive bids until January 11 for the construction of a 65 x 130 ft. fireproof laboratory building for the Physics Department. Estimated cost, $60,000. W. Scott Dunne, Department of Architecture, architect.

FT. WORTH—Armour & Co., Union Stock Yards, Chicago, Ill., will build a six story, 220 x 300 ft. curing plant, having a 5,000,000 lb. capacity, in connection with the improvements which it plans to make to its packing plant. Total estimated cost, $500,000.

FT. WORTH—The Baltic Refining Co. has awarded the contract for the construction of a concrete and steel oil refinery, having a daily capacity of 500 barrels, to the Bryce Building Co., 909 Throckmorton Building. Equipment for refining petroleum into all finished products, including gasoline, kerosene, lubricating oils and wax will be installed in same. Estimated cost, $750,000.

FT. WORTH—The El Dorado Refining Co. will build a 5000 barrel refinery here. Estimated cost, $1,000,000.

FT. WORTH—The Evans Thwing Co. will build a refinery, having a capacity of 3500 barrels, on the site of the Tarrant County poor farm. Estimated cost, $600,000.

FT. WORTH—The Army and Navy Departments, Washington, D. C., will build a plant adjoining the Government experimental plant here for the manufacture of balloon gas. Estimated cost, $5,000,000.

FT. WORTH—The Sterling Oil & Refining Co., 511 Beacon Building, Wichita, Kan., will build an oil refinery here, to have an initial capacity of 5000 barrels. W. McGinley, president.

LA PORTE—Palmer Hughes, 912 Oxford St., and associates, have purchased a site near here and will build an oil refinery having a daily capacity of 600 barrels.

Virginia

LYNCHBURG—The Sanitax Dry Cleaning Co., Main and Chestnut St., has awarded the contract for the construction of a one story, 50 x 69 ft. dry cleaning plant to W. B. Snead & Co., 1321 Main St. Estimated cost, $15,000.

NORFOLK—The Norfolk Glass Manufacturing Co., 564 Church St., will build a plant near Berkley St. for the manufacture of glass specialties. Estimated cost, $200,000.

NORFOLK—The Virginia Fruit Juice Co., 4-12 Washington Ave., has awarded the contract for the construction of a two story, 44 x 65 ft. vinegar plant, to J. H. Pierce, Law Building.

PORTSMOUTH—The Southern Brass Works, National Bank of Portsmouth Building, has awarded the contract for the construction of a one story, 40 x 67 ft. extension to its plant, to John W. Hoffler, 504 5th St.

Washington

LOON LAKE—The Loon Lake Copper Co. will build a concentrating mill, to have a daily capacity of 100 tons. Estimated cost, $45,000. C. J. Stone, manager.

VALLEY—The Admiral Mining Co., Rookery Building, Spokane, has been authorized to issue $75,000 bonds, $50,000 of which will be used for concentrator to be installed here, if development work justifies same. J. Richard Brown, manager.

Wisconsin

JEFFERSON—The Board of Commissioners of Jefferson County will install a private water system and septic tanks in the two and three story, 100 x 150 ft. sanitarium which it will build. Estimated cost, $75,000. O. C. Uehling, First National Bank Building, Milwaukee, architect.

MILWAUKEE—The Milwaukee Gas Light Co., Milwaukee and Menominee St. will alter its gas plant. Estimated cost, $65,000.

MILWAUKEE—The Milwaukee Paper Box Co., 400 Florida St., will build a five story, 120 x 144 ft. manufacturing building and garage, on Pierce and Muskego Sts. Estimated cost, $225,000. Schnetzky & Son, 105 Wells St., architect.

RACINE—The Osborne Casting Co., Layard Ave., will build an addition to its core room, foundry and auxiliary building. Estimated cost, $20,000. C. G. Holmes, general superintendent.

Nova Scotia

HALIFAX—The Canada Metal Co., 37 Fraser Ave., Toronto, will build a plant here. Estimated cost, $50,000. W. G. Harris, preseident.

Ontario

BOSTON CREEK—The Miller Independence Mining Co. has increased its capital stock and will build an addition to its existing plant, and is in the market for crushing and grinding machinery and flotation mill and electrical equipment. George Miller, superintendent.

Quebec

CLARK CITY—The Gulf Pulp & Paper Co. will build a paper mill. Estimated cost, $10,000. T. Clark, superintendent.

Mexico

CUSIHUIRIACHIC—The Compania Minera del Mirasol will build a 200-ton concentrating mill. C. B. Clyne, Mills Bldg., El Paso, Texas, is preparing plans.

Manufacturers' Catalogs

THE JEFFREY MANUFACTURING CO., Columbus, Ohio, calls attention to a 72-page catalog, No. 244, on the Jeffrey bucket elevators in standard sizes. Forty pages are devoted to details of elevators selected out of numerous styles used in the handling of a wide range of materials in practically every industry of the country and known as Standard Elevators. A page is given to each Standard Elevator, which is illustrated, both in perspective and in line drawing, giving dimensions. There is also an illustration showing the chain and bucket used in that type of elevator, and at the bottom of each sheet is given a full list of all specifications applying to that particular elevator. This attractive catalog is ready for distribution to the trade.

THE INDEPENDENT FILTER PRESS CO., INC., Brooklyn, N. Y., has issued a catalog on the Indefilco filter press, and calls attention to patent No. 1,282,414 on an improved field plate, which is illustrated and described.

THE AMERICAN ZINC, LEAD & SMELTING CO., St. Louis, Mo., has just received from the press a 36-page booklet dealing with Azo zinc oxides, which will be sent upon request to any member of the trade.

The Outlook of the Optimist

NOW is the time to be optimistic. And we will be if we are thoughtful, for it is mainly the thoughtless and heedless who comprise our minority of alarmists and pessimists. Our country has just completed the most gigantic task ever set for it since the day when it achieved political independence. By the same token it faces, with the other great nations of the world, the most momentous problems in human history. Having been successful in overcoming the military forces of the enemy by performing stupendous tasks of organization and production, are we to face less resolutely and with less hope, confidence and courage the problems of government, of labor, of food, of production and distribution, of demobilization and reconstruction?

Let us think for a moment and try to realize conditions that are average and general instead of those that are isolated and specific. The pessimist says there is a shortage of this or that. The optimist retorts that the shelves of the world are bare—and he is right. The pessimist says that the Governments of the world have destroyed billions of dollars worth of material property and that we face ruin. The optimist replies that the people of the world hold securities for billions of dollars, and are richer thereby, with more floating capital and quick assets as buying power than they ever had before. The pessimist sees parts of the world ragged, shabby, hungry, oppressed and distressed. The optimist knows that they are but waiting to spend their money for clothing, food, the necessities and even the minor luxuries of life and that the ideals of the world's leaders promise better conditions for mankind than we have ever known.

For several years we have had unprecedented prosperity. Those who are far-seeing know that the next few years also will be years of plenty. It is merely the gulch, the chasm that lies between these two heights, that gives pause to the thoughtful and brings visions of panic to the thoughtless. The spanning of that gulch can be accomplished just as surely as we raised an army of several million men, just as surely as we turned our industrial machinery from peace to war, just as surely as we raised billions of dollars to support and supply our armies. And we accomplished those things by creating a spirit of confidence in our ability to do them, by uniting the whole country in the thought that although the task was stupendous it nevertheless was feasible.

This is what we must do now with regard to the future. We know that prosperity is just ahead. We must not delay its coming, or rather break its continuity, by becoming alarmed at high wages or isolated

instances of over-supply. Production must be continued and stimulated because there is going to be the demand. We must be glad to see high wages, but we must get an equally high return for them. All standards are higher than they were four years ago—standards of living, wages, production and morals, and there is every reason why they should be maintained on that high level. The need of the world is a new vision, adjusted to the new order. Reconstruction does not mean a return to the old, but an adaptation to the new and best that has grown out of our troubles. Optimism is the order of the day, and the duty of every thinking man is to see clearly and largely and spread the gospel of confidence and our ability to achieve.

Faith in Our Friends and Allies Across the Atlantic

LET'S begin with a parable. Once there was a man who had a son, and the son was a lively boy. He was full of zip and ginger, and as he grew up he displayed great curiosity to know what was going on in the world. Now the father was a cautious man and, knowing the temptations to which all flesh is heir, he admonished the younger one against the many dangers which beset his path. He said to himself that one cannot be too careful, and he watched in secret and listened diligently to whatever reports were brought to him by others, wherefore he was convinced of his son's waywardness even until his suspicions were greater than their warrant. So disagreements arose between father and son and neither trusted the other. And the son persevered in the pursuit of evil, while the father ended his days in sorrow and bitterness.

There was also another man whose son was like unto the first, but the father had faith in him and trusted him. When he was wayward and became entangled in difficulties, his father helped him and sympathized with him, remembering his own early days. Neither would the elder man listen to any evil word that was spoken of him, for, said he, he is mine own son and I should be false to withdraw my faith from him. In the process of time the young man mended his ways and persevered in the paths of righteousness, so that great honors were bestowed upon him. And the twain spent their days in amity and delight. Selah.

Now we have the beginning of another year with victory in our hands, and we may well ask ourselves what we shall do with it. The problems are so many and so great that we are all as little children before them; while the responsibilities are so ponderous that every one who participates in American citizenship has obligations as great as those of a father. What, then, shall we do with this victory? It is not ours alone. Have we earned more of it than our brothers of England, or France, or Italy, or Belgium? We have more of its fruits, but, much as we have paid, our cost has been less than theirs. We cannot deny and we should not forget that for three years they fought our battles. While they were doing this we sold them munitions and thus became the great creditor. Now a great creditor also has obligations like those of a father. Shall we hold fast to our faith in Englishmen and Frenchmen and Italians and Belgians just as we did when our boys were fighting beside theirs? They have borne much and they are sore wounded. They are very likely to say things and do things and want things that do not seem fair to us. It is excellent to let any one who disagrees talk himself out. Then if we do not respond in anger and thus put him on the defensive, he will not mean everything he has said, after all.

We can carry chips on our shoulders and tell our allies in war that we saved their skins and we can boast and browbeat everybody until we look and sound like so many Germans of the style of 1913. We can incline our ears toward WINSTON CHURCHILL and suspect that Great Britain is resolved to rule the seven seas with a rod of absolute authority and that none but Englishmen may command a ship and none but Scotchmen may operate its engines. There are always enough Fenians and German propagandists running loose to urge us to beware of this hazard that does not exist and never will unless we conjure it up with the help of hate and malice. There are vast possibilities of the development of electrochemistry in France, and because we must hustle to keep our end up in this respect (which is a good thing for us), we can declare that France is more of an enemy than a friend. And then, once our suspicions are well aroused, there's no reason why we should not shiver and fear lest the Belgians be getting ready to eat us up. It would be quite as reasonable. Once we get to thinking along this line it is easy to go on. The Belgians were the ruination of Germany, and Germany was a great nation in her day. Broad is the road and easy the way that leadeth unto trouble.

On the other hand we can keep on believing in our friends across the sea even when things look all wrong and everybody seems disposed to put up tricks against us. Of course we must use our heads and look after our affairs, because things are so ordered in this world. Intelligence is expected. That is the reason guardians are appointed for incompetents. But the main thing is to keep good natured over our job, to make only fair and just proposals and to hold in mind the vast difference between wisdom, which is safe, on the one hand, and shrewdness, which is explosive, and suspicion, which is poisonous, on the other. That second father in the parable knew very well what the boy was up to, but his virtue was that he would not listen to anything that might make him angry. He knew all the time what he was about; but he kept up his faith in spite of everything. That is what we must do.

Scrutable in the Penultimate

THE *Canadian Chemical Journal* takes us severely to task for expressing regret that the president of the Honorary Advisory Research Council of Canada, Dr. A. P. MACALLUM, should hold the opinion that, while it may be inscrutable in the ultimate, there are reasons why international co-operation is inadvisable.

Now the last thing on earth that we want to do is to foment discord, and one of the easiest ways to cause it is to argue that a kindly neighbor who criticises is in error. We do not and did not mean to discourage Canada in research; in our hearts we want to encourage it, but if our Toronto neighbors conclude from our utterances that we indicated a slant toward such discouragement, the best that we can do is to protest our innocence. We want to see Canada among the world's

leaders in science, in the arts, and in the good things of life, with prosperity included.

We have searched our souls in wonder how, if this intimation which we did not mean and cannot see, is present in our comments, it happened to hide itself there. They are keen readers in Canada, and we respect their scholarship, literary as well as scientific. Knowing well how unconscious motives play the very devil with the best of us, we have reached the conclusion that, if the meaning is there, our words may have been tinctured with jealousy. We are rather fond of turning phrases ourselves, and we confess that we never thought of the expression "inscrutable in the ultimate" until Professor MACALLUM invented it.

We try to give our readers as fine a chemical and metallurgical journal as there is in the world, but the barriers of speech do encompass us all. And if Canadian professors bring out novelties like "inscrutable in the ultimate," we cannot resist the temptation to use the expression in comment. Nevertheless we maintain certain reservations of conservatism ourselves, for lately we decided not to print an article involving "foremanizing" and "functionalization." At the ruling prices of metals we do not want to strain our type. Nevertheless we would rather buck the antimony market than leave anything unsaid in support of proper modesty, or that might hinder us from the enjoyment of amity among our colleagues.

Capacities Well Aligned in the Iron Industry

THE obvious fact that the steel industry emerges from the war with a much greater plate rolling capacity than existed before the war might suggest that the war disarranged the alignment of capacity in the iron industry as a whole in a number of respects. A scrutiny of the situation indicates, however, that really the industry emerges from the war, with all its intensive and extensive new construction, in remarkably well balanced shape. Claims to the contrary are made, but they come from the commercial rather than the technical ranks. Some merchant blast-furnace men have undertaken to argue that there are not enough blast furnaces to go around and that if the steel mills are called upon to operate at capacity pig iron will command a higher price in the market, in relation to billets, than has obtained in the past.

Considering commercial capacities, ability to produce material under normal and reasonably favorable conditions, the existing pig iron capacity may be taken at 45,000,000 tons a year and the capacity in steel ingots and castings at about 50,000,000 tons. To the uninitiated, possessed merely of a knowledge that pig iron serves the double purpose of making iron castings and making steel, this might seem quite awkward at the outset, but the fact is that "steel production" as commonly reported in the form of ingots merely represents the record of the ingot scales. The material is subject to scaling and shearing, and while the scale is lost in the balance, when it goes through the blast furnace and appears as pig iron production, the scrap goes through the blast furnace and makes its second trip over the ingot scale.

The year 1916 was quite a normal one in respect to operations in the iron and steel industry. There were 39,434,797 tons of "pig iron" produced, of which 32,522,078 were bessemer, basic, low phosphorus, ferromanganese and spiegeleisen, and 6,912,719 tons were foundry, ferro-silicon, malleable, forge and unclassified. There were produced 41,401,917 tons of steel ingots and 1,371,763 tons of steel castings, making a so-called total "steel production" of 42,773,680 tons. Of finished rolled steel, however, including unfinished steel exported, there were produced only 30,557,818 tons.

The first named, pig iron, 32,522,078 tons, may be considered steel making iron for the purpose of this analysis. It represented 76.0 per cent of the weight of the 42,773,680 tons of steel ingots and castings produced. By the same proportion, 50,000,000 tons of steel ingot and casting capacity at present require 38,000,000 tons of pig iron. With 45,000,000 tons blast furnace capacity there are left 7,000,000 tons of pig iron for gray iron and malleable foundries and puddling furnaces. The amount in 1916 was 6,912,719 tons. That the demand does not grow as does the demand for steel products is indicated by the fact that the corresponding amount in 1910 was 6,748,886 tons.

This makes a clear case that according to precedents there is no shortage of pig iron in prospect, but there are two other facts which indicate that if there is any disturbance in the balance it is in the other direction. In 1916 the United States exported 212,765 tons of scrap and 607,236 tons of pig iron. It can hardly be maintained that, from an economic standpoint, we ought to export those materials. Why not export iron ore, also coke, or, better still, coking coal? The second fact is that the present new construction program involves about 1,000,000 tons of steel ingot capacity and materially more than 1,000,000 tons of pig iron capacity, whereas 760,000 tons of pig iron would take care of 1,000,000 tons of steel ingots.

These computations are not conclusive as to what will occur. What they do show is that there is no basis at present for concluding that pig iron will be scarce relative to steel or that it will be particularly plentiful relative to steel. When it comes to the test, under favorable conditions, blast furnaces, steel making departments and steel rolling departments are all more or less likely to exceed their ratings or break previous records, and no one can tell which department would come out ahead in the race.

As to there being a proper balance at this time between steel making and steel rolling and finishing capacity the case is not so clear. Throughout the war, it is true, rolling capacity was found for all the ingots produced, even the altogether unconventional ingots produced in steel casting plants as a war-time measure, but there was much shell steel produced, with little rolling, much of it passing to the forge shop in large sections. An abnormal tonnage of plates was produced, but such a tonnage will still be required. If, however, any shortage of rolling capacity develops it can be remedied much more readily than a shortage of pig iron or steel making capacity.

Thus the iron and steel industry is well balanced within itself. Whether it is well balanced against commercial demand for the product, when its capacity is 114 per cent greater than the output in 1906, an extremely good year in its time—that is another story, on which the future will throw light in due time.

Readers' Views and Comments

Ferromanganese

To the Editor of Chemical & Metallurgical Engineering

SIR:—I observe in the Dec. 15 number on page 794, under the heading of "Missing Page From the Blue Book Speller," your article on the subject. You certainly could not hit the target and ring the bell better than you did in this article. I will endeavor to answer the question that you mention.

If manganese ferro-alloy is dropped into an empty hot ladle and the ladle then filled from the crucible of steel, the mixture will be perfect, as it requires between ten and forty seconds to completely fuse the manganese ferro-alloy. I find that this method makes a stronger casting and absolutely no segregation takes place.

A. R. BALCOM.

. Toronto, Canada.

Colloids in Flotation

To the Editor of Chemical & Metallurgical Engineering

SIR:—In an article entitled "Colloids in Flotation," *Mining & Scientific Press* of Oct. 12, I endeavored to explain some vagaries of the flotation process. In your issue of Nov. 15, Mr. A. Schwarz has dissected the article and subjected its author and his profession to some abuse for calling a certain substance colloidal matter. I am offering no apologies for having written the article, but would like to clarify certain points that received a broadside of condemnation.

The statement that I had "written with a total ignorance of the actual meaning of colloid chemistry" was clearly ill advised in view of the opening statement of my article in these words "the very fine amorphous material in crushed ore usually spoken of as colloids or colloidal matter." Colloidal matter is a term used in the absence of a better one for this particular substance. It is fine, amorphous, difficult to settle, hard to filter out, sometimes passing through the filter very much as does the water to which it imparts a velvety sheen. That it may contain colloids is recognized by the United States Bureau of Mines[1] which notes the presence of such colloids as kaolin, iron, aluminium hydroxide, tungstic acid, molybdic acid; and more particularly colloid silica as noted by Courtenay De Kalb[2] in this statement, "Common hydrophilic colloids are soaps, gelatin, albumin, casein, and silicic acid. The last is produced in mill pulp as a result of attrition on the ore. The longer and the more finely the ore is ground the larger will be the hydrophilic gel-colloid present in solution." Whether these colloids are flocculated or not the subject under discussion can be referred to, even in the presence of granular material, as colloidal matter without necessarily being ignorant of the meaning of colloid chemistry. It is interesting to note that the conclusions reached in technical paper No. 200 of the United States Bureau of Mines are almost identical with those stated in my article as to the deleterious effects of colloids in flotation. Here are the two conclusions, and it matters but little which you take. "If a considerable amount of colloidal material is present, its elimination, or at least the elimination of its effects, will be necessary," and "the elimination of all, or nearly all colloidal matter very likely would end most of our flotation troubles."

Mr. Schwarz proceeds to tell us that "beyond all question of doubt the flotation process is absolutely fundamentally based upon the colloids from oils, tars, intermediate products, and the like used." That may or may not be so, but we do know that oils, tars, and coal tar intermediates are not necessarily effective agents in selective flotation. They may be effective frothing agents, but the production of froth is not necessarily effective flotation. I have seen froth a foot deep that carried relatively less mineral than the original ore. In my work on feldspathic ores I have reduced the froth from a cross-section area of 300 sq.in. to 2½ sq.in., and thereby increased the recovery 100 per cent. Froth is not sufficient in itself, nor is a colloid. If a colloid were sufficient, it should be feasible to float the minerals with the colloids in the ore. If the presence of colloids in the ore is denied, and a colloid is "absolutely fundamentally" essential, how can we explain the successful flotation of ores by the use of the alkali chlorides?

We are greatly in need of information as to "Why is flotation?" As I mentioned in an article on flotation tribulations[3] one should study his problem in the light of the theory applicable, but that in flotation while everybody has satisfactory results, nobody has a satisfactory theory. Ingenious theories have been advanced and upheld with as much dogmatism as Mr. Schwarz holds the colloid theory, nevertheless they have perished. The colloid theory has much merit, but that it is "absolutely fundamentally" so is open to question at this early date. Theories should be accepted in view of the percentage of the total known facts they comprehend, and never in our time as absolute. Centuries of experience have taught us that any prevailing theory is one that merely comprehends more known facts than any other kindred theory.

The importance of research work in colloidal chemistry or in any other line of study is to be emphasized, and was so stated in my article, but qualified in these words, "by those in position to do it." Which again brings up the question of research work with reference to applied metallurgy. If one canvasses the whole world of concentrating mills and cyanide plants, he will find but few laboratories sufficiently well equipped for carrying on the research work that the subject demands. Also he will find very few men sufficiently well prepared for this work who have the time to devote to it. Usually the man detailed to get results, whether manager, superintendent or foreman, has his hands well filled in keeping the plant in operation, in keeping up supplies and labor, and in performing the simple well known tests incident to his process, and has neither equipment nor time for special research work. He even may be reduced to the expedient of carrying out his cyanide tests with beer bottles tied to classifier gears or thrown upon concentrating tables for the necessary agitation, or of making oil stills from odds and ends of sleeves, plugs and re-

ducers. While excellent results have been obtained in this way, it is inconvenient and a waste of precious time. It is noteworthy, however, that in spite of these limitations nearly all the successful contrivances such as filters, agitators, concentrating tables, furnaces, classifiers, etc., are the result of the patient efforts of those same men characterized by Mr. Schwarz as of "medieval ideas"—the more honor to them! On the other hand, centrally located and privately equipped laboratories or universities with well appointed research laboratories and well stocked reference libraries, and highly trained research men should assume the task of working out the theories and problems necessitating much study and elaborate equipment. That the universities, the United States Bureau of Mines, and the men in the mills cooperating in this work are doing a service of merit is well known, and it is commendable that but very rarely has a member of one branch of the profession had the indiscretion to refer to other members as "ignorant" and "medieval." JACKSON A. PEARCE.

Berkeley, California.

Analysis of Ferromanganese

To the Editor of Chemical & Metallurgical Engineering

SIR:—I am submitting herewith a scheme for the analysis of ferromanganese, which I have used for some time and find entirely satisfactory. When flasks, pipettes and burettes are properly standardized, I consider the Bismuthate method accurate.

A one-gram sample is dissolved in 50 cc. nitric acid, (sp.gr. 1.13) by boiling gently in a covered beaker for about 30 minutes. Transfer to a liter flask and make up to mark. Pipette out 25 cc. into a 250 cc. Erlenmeyer flask and determine manganese by the Bismuthate method. A N/10 solution of potassium permanganate gives a solution of convenient strength, and a ferrous ammonium sulphate solution of almost equal strength is made by using 39.2 grams of the salt and 50 cc. sulphuric acid made up to one liter.

Dissolve a 0.500-gram sample in a casserole with 50 cc. nitric acid (sp.gr. 1.13), and evaporate to dryness. Ignite over a free flame. Cool, take up in hydrochloric acid, evaporate to dryness again and bake for a few minutes at a low temperature. Take up in dilute hydrochloric acid, bring to boil and filter off siliceous matter. Determine iron from filtrate by titrating with N/10 potassium permanganate solution. Ignite residue, weigh as silica and calculate to silicon. This method is accurate enough for metal low in silicon. For metal containing above 1 per cent of silicon it is recommended that the weighed ignited residue from this or a sodium peroxide fusion be evaporated to dryness with a few drops of sulphuric acid and 4 to 5 cc. hydrofluoric acid, ignited slowly and weighed. The difference in weight multiplied by 0.4702 gives the per cent of silicon.

Treat 1.63 grams as for iron and silicon. After evaporating to dryness with hydrochloric acid, add just enough of the acid to dissolve the residue. Warm and convert into nitrates by adding 20 cc. of nitric acid and evaporating twice down to syrupy consistency. Then add 20 cc. of nitric acid, evaporate to about 12 cc., dilute to about 100 cc. with hot water and allow to cool. When solution is between 65 and 75 deg. C., filter into a 250 cc. Erlenmeyer flask, then add, filtering, 60 cc. of molybdic acid solution. Shake for a few minutes, and set aside in a warm place for about one hour. Filter on a weighed Gooch crucible, washing with 3 per cent nitric acid solution, dry and weigh. The residue contains 1.63 per cent phosphorus, therefore each milligram found corresponds to 0.001 per cent phosphorus in the metal.

That Missing Page From the Blue-Back Speller

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read the article under the above title in CHEMICAL & METALLURGICAL ENGINEERING of Dec. 15 and am surprised to learn that any of the steel plants are still using the archaic method of adding lumps of ferromanganese to the steel in the ladle.

I was with the Robert W. Hunt Co. at the time Capt. Hunt started his then novel inspection of rails from the furnace to the loading dock. During this time I was afforded every opportunity for inspecting the open-hearth end of steel-making. It was a part of my duties to follow each heat all through the mill.

Col. W. P. Barba has good grounds for seriously questioning the additions of lump ferromanganese in the ladle. There is no need to go into the rather difficult investigation of how long it takes a piece of ferromanganese of given size to melt in a bath of steel. This would be a somewhat difficult matter to determine. All that is necessary is to take samples from different parts of the heat to which the lump metal has been added. Samples from the first, middle and last ingots should tell the story. I have found that, given a good tap and the ferromanganese added in small pieces just fast enough and not too fast, you may get the manganese distributed and well mixed through the steel. This combination of circumstances is not, however, often realized.

In most cases the ferromanganese is added too rapidly or in case of exceptionally large charges too slowly. In either case the manganese is not distributed evenly through the metal no matter how much current you may get in your ladle. Manganese once thoroughly mixed with the molten steel will not segregate—it must be thoroughly mixed in the first place.

In one plant it was the practice to add ferromanganese in pieces from $\frac{3}{4}$ to 1 inch in the ladle. In the case of this plant I found very considerable variations in manganese content between the first and last ingots poured. Sometimes the first ingot would carry as low as 0.5 per cent manganese and the last 1.5 per cent. The test from the middle of the heat carried around 1 per cent manganese and was apparently all right. In another plant, one with the best of metallurgical practice with this exception, i.e., that about half of the manganese was added in the ladle, I found considerable variations in the manganese content but not as great as in the case mentioned above. The management of the last mentioned plant made a careful investigation of the question and as a result installed an electric furnace so as to melt the ferromanganese and add it in a liquid state as the furnace is being tapped. This practice gives a thorough distribution of the ferromanganese and saves besides about 20 per cent of the manganese, which under the former method was lost in the slag.

Great Falls, Montana. R. A. DRISCOLL.

Rossiter W. Raymond

DR. ROSSITER WORTHINGTON RAYMOND, mining engineer, editor, author and lawyer, died suddenly of heart failure, on the thirty-first of December at his home in Brooklyn. Dr. Raymond would soon have been an octogenarian, having been born in Cincinnati on April 27, 1840. He spent his childhood at Syracuse, N. Y., and after completing the grammar school grades there, he took a two-year course at the Brooklyn Polytechnic Institute, of which his uncle was president at that time. He was graduated with an excellent record in 1858, and immediately went abroad. While in Europe he attended Heidelberg and Munich Universities and studied mining engineering at the Royal Mining Academy, Freiburg, Saxony.

At the opening of the civil war, he returned immediately to America, enlisted in the Federal Army and served as aide-de-camp, with the rank of captain, on the staff of Maj. Gen. J. C. Fremont, by whom he was officially cited for gallant and meritorious conduct during the strenuous campaign in Virginia which became well known in history, the first time in warfare where underground excavations and mining operations were used in military attacks on fortifications.

ROSSITER W. RAYMOND

Immediately after the close of the war, he returned to New York and engaged in practice as a consulting mining engineer and metallurgist and in 1867 became editor of the *American Journal of Mining*. As his income as editor was not sufficient, Dr. Raymond accepted important additional duties; in 1868 he was appointed United States Commissioner of Mining Statistics, which position he eminently filled, issuing annually for eight years "Reports on the Mineral Resources of the United States West of the Rocky Mountains," and from 1870 to 1882 he taught economic geology at Lafayette College. Dr. Raymond was one of the first to realize the value of professional societies and was not only a charter member of the American Institute of Mining Engineers but devoted the best part of his life to the promotion of its welfare, serving as president in 1872 and 1874; vice-president, 1871, '76, '77 and secretary from 1884 to 1911 and secretary emeritus for the remaining eight years of his life. In 1873, he was appointed United States commissioner to the Vienna International Exposition and during his stay in Europe was invited to address the Iron and Steel Institute at Liege, Belgium.

From 1875 to 1895 Dr. Raymond was consulting engineer with Cooper & Hewitt, proprietors of the New Jersey Steel & Iron Co., the Trenton Iron Co., and numerous iron ore and coal properties. As president of the Alliance Coal Co. and through his association with the coal operators of Pennsylvania, especially with Frank B. Gowan, he became well acquainted with the facts concerning the memorable campaign against the "Molly Maguires." His activities in regard to labor questions made him known as a courageous and fearless opponent of all tyranny practiced in the name of labor and his articles on "Labor and Law," "Labor and Liberty," etc., published in the *Engineering and Mining Journal* at the time of the Homestead riots attracted world-wide attention.

Dr. Raymond was a deep student of legal matters and was admitted to the bar of the Supreme Court of New York State, and of the Federal District and Circuit Courts in 1898 at the age of fifty-eight. He confined his practice to mining and patent law, in the former of which he was a great authority and on which he gave lectures at Columbia.

As editor of the annual volume of *Transactions* of the American Institute of Mining Engineers, Dr. Raymond reached the highest standard of achievement. He was a master of the English language and had the ability of perfecting the scientific contributions of others so that the words ran fluently, clear, fresh and to the point. He was a constant contributor in the *Engineering and Mining Journal*, where will be found numerous articles both signed and anonymous, which shall always be appreciated for all days to come by the many who have a thirst for information to quench.

In 1884, he prepared for the United States Geological Survey a history on mining law, which was subsequently translated into foreign languages. It is rare that so versatile a person reaches a high degree of excellence in all his endeavor, but it can be easily verified by any of his associates that he did the many things thoroughly. His remarkable personality has become a cherished memory of many members of the Institute and his career a monument among the engineering profession.

Dr. Raymond was an honorary member of the American Philosophical Society, Society of Civil Engineers of France, the Iron and Steel Institute and the Institution of Mining and Metallurgy of Great Britain, and many other technical, scientific and social organizations both at home and abroad. In 1869, shortly before his taking the chair of economic geology at Lafayette, that college conferred upon him the degree of Ph.D. The degree of LL.D. was conferred upon him by Lehigh in 1906 and the University of Pittsburgh in 1915.

In 1911 Dr. Raymond received from Japan the decoration of Chevalier of the Order of the Rising Sun, the highest given to foreigners not of royal blood, in recognition of his advice and assistance to Japanese engineering students in this country.

Dr. Raymond married Sarah Mellen Dwight at Brooklyn on March 3, 1863, by whom he is survived. He is also survived by a daughter, Mrs. H. P. Bellinger, who lives at Syracuse, the childhood home of our beloved engineer, author, editor, lawyer and genius.

Western Chemical and Metallurgical Field

Recovery of Potash From Molasses Fermentation Liquors

By E. Humboldt

THE PLANT of the Mason By-Products Co., on the north shore of San Francisco Bay, is one of the recent additions to the rapidly growing list of new industries on the Coast. Started last fall to take care of the waste of the distillery of the Mason Malt & Whiskey Distillery Co., it is turning out a large amount of stock feed and crude potash for fertilizers. Later on it is expected to produce ammonium salts, acetates, ether and other solvents, and generally to utilize as far as possible all the contents of distillery waste. The distillery is operated exclusively with molasses, both cane and beet, coming from California and the Hawaiian Islands.

At the present time, owing to poor transportation, it is absolutely impossible to segregate the raw material properly. As most of it is received badly infected with bacterial growths and contaminated with formaldehyde and sulphites, the fermentation is rather difficult

PLANT OF THE MASON BY-PRODUCTS CO.

to control. Lack of time has so far prevented any sterilization of the molasses, but a large sterilizer is being erected, which will take care of all the material used day by day, and it is expected that much better results will be attained as soon as it is put in operation. On this account, the composition of the mash varies enormously and the specific gravity of the waste oscillates between 1.04 and 1.06. Consequently it is impossible to give an analysis representative of its contents. As a rule, by calcination it will yield from 4 to 6 per cent of ash containing 36 to 38 per cent of potash.

For various reasons it has been found convenient to separate the yeast before recovering the potash from the waste or slop. It is settled out, pressed and dried, and sold for chicken and stock feed. It contains from 30 to 40 per cent proteids, figured on dry basis, about 15 to 20 per cent ash, some phosphoric acid and a little potash. Cattle are very fond of and seem to thrive on it, provided it is properly used as part of a well-balanced ration. Experience shows it is particularly well adapted to the feed of dairy stock, as it increases the milk production. The amount recovered is not large, and the local market will easily handle the whole output. At the present time no effort is being made to recover anything but the potash, and consequently the slop is stored in a battery of six 150,000-gallon tanks (six more are being built), which deliver it as needed to the evaporating furnaces.

The process is very simple, consisting merely of evaporating the liquid as far as possible, generally about 30 deg. B., then burning it in a reverberatory furnace. These furnaces, four in number, are of the Porrion type, but modified to conform to later designs and to obviate many disadvantages of the old type, being easier to clean and of much larger capacity. Each one has three parts, evaporating chamber, calcining pans and a large combustion intermediate chamber. The calcining pans are fitted with oil burners, and the waste heat is used exclusively for the evaporation. The evaporating side is a large shallow pan, made entirely of brick and arched over, in which the slop is fed continuously; a series of revolving paddles keep the liquid in constant motion, producing a heavy spray, which accelerates the evaporation. Owing to the large combustion chamber between the sections of the furnace, the hot gases coming in contact with the evaporating slop are clean and free from soot, and the temperature at the breeching of the stack very seldom rises above 200 deg. C. It is necessary to admit a large excess of air to the burning pans, which must be opened from time to time for stirring and unloading. To secure the proper draft, each furnace is provided with an exhaust pan leading to the stack.

The feed into the evaporating pan is regulated by automatic floats, and but very little attention is required beyond occasional cleaning, charging a liquid of about 7 to 8 deg. B. and delivering it at from 25 to 35 deg. B. The calcining is done by direct flame up to the time when the charge begins to burn, when the fuel is cut down and a large amount of air admitted. With a little stirring to help, the operation is quickly finished, and the black, blazing clinkers are dumped out and wheeled onto a platform, where the combustion completes itself. As soon as the mass is cool enough to handle it is run through a pulverizer and sacked for shipment.

No attempt has been made thus far to leach the clinker to prepare concentrated potassium salts, as the demand for fertilizer material is much larger than the supply and the foreign char and insoluble ash answer filler purposes for this use. The furnaces are provided with fuel meters, recording draft gages and thermometers, and a perfect control and check of their work is at hand at all times. Besides, the whole installation is run by electric power and is very compact and easily handled. Of the four furnaces built, three are in constant use, the fourth being ready for emergency or switched on when one of the others needs cleaning.

The repair work, after four months' operation with unskilled labor, and general upkeep are fairly heavy, as is usual with most new plants. With proper care and supervision, the three running furnaces will take care of about 85,000 to 90,000 gallons of slop daily and can easily handle all the product of the distillery.

Industrial Efforts in France During the War

A View of the Conditions Under Which the Chemical Industry of France Has Developed During the War — Coal Tar Dyestuff, Synthetic Nitrogen, Alsatian Potash, Algerian Phosphate, Soap and Oil Industries Have Great Possibilties

By Georges Maoussa*

WHEN, a few weeks ago, I had the honor of being requested by Dr. Baekeland to discuss a subject in which I am so deeply interested, nobody dared to hope that this war would end so soon, and that the problems brought forth by the late events would call for such immediate and earnest attention.

When in 1914 the Germans started this war, they thought of conquering the whole world. Besides other things, this military conquest was to establish, or rather impose definitely, an economic supremacy.

Constant toil and tenacity—we have to acknowledge these qualities of the Germans—and unscrupulous commercial methods had opened to the Germans the markets of the whole world, where they had created for themselves one of the first places. If I recall the agreement for the sale of aniline and, in another instance, the sale of fast dyestuffs in this country, it is needless for me to dwell any further on the importance of the commerce in the hands of the Germans and the moral value of their proceedings.

More than in any other field, the Germans had surpassed other countries in the manufacture of organic chemical products. Thanks to this industry, the Germans maintained for a long time material superiority in practical warfare. For obvious reasons I shall not be able to describe the wonderful progress of chemistry in the field of war necessities. In other branches of chemistry the improvements were not less marvelous, and if Germany hopes to find again a hegemony in that line, she will be bitterly disappointed. Be it in Italy, Japan, England, the United States or France, hidden and even unsuspected energies were awakened. Plants were built, and in four years we made ourselves independent of Germany.

Chemical Industry to Have Hard Battle

During the past years the Germans themselves have been far from inactive, and our young industry shall have to fight a hard battle. A trust including all the German chemical plants awaits but a signal to overflow the world at the lowest price with great quantities of finished products now stored in neutral countries.

With a violent commercial offensive, such as the military one we saw in 1914, they will attempt the destruction of this new industry. Generous support of the consumers and protection by putting high duties on German products will help us to face the first difficulties, but only by selling better and more economical products shall we maintain our position in the long run.

For this purpose an agreement between the producers is indispensable. We shall have to avoid the scattering of our efforts, the manufacturing of the same products by many people and competition in the world market. First of all, each country should start only the manufacture of products for which its geographical situation, its mining resources and the adaptability of its workmanship make it desirable.

During the war such reasoning could not hold. But now there is going to be a large overproduction of all the war chemicals, the result of which would be, judging from the normal course of events, strong competition and precipitate decline of prices. It is urgent to figure out what we can expect from each country, and what has already been accomplished.

Coal-Tar Industry

At the eve of the war the situation of the coal-tar industry in France was nothing less than cheerful. How wonderful had been France's contribution at the start of the synthetical dyestuffs industry!

After the discovery of the mauveine by Perkin, the Frenchman Verguin produced fuchsine at Lyons in 1859. Three years later St. Denis, a suburb of Paris, saw for the first time the manufacture of aniline on a large scale by the method of Béchamp. In 1873, the Cachou de Laval inaugurated the series of sulphur dyes and Zacharie Roussin in 1875 was one of the first to make diazo sulphonic acids.

What is left of this promising start? A few small factories operate with small sales, some have disappeared, while others, having kept their French names, are only branches of important German firms.

Under these conditions the private industry was not in the least prepared to meet the enormous requirements of modern warfare. But these difficulties did not dishearten us. Under the presidency of the dean of the French chemists, M. Albin Haller, Member of the Institut, competent chemists assembled at Paris, Lyons and Bordeaux. Manufacturers of Lille and Roubaix, who had seen their factories burned or occupied by the Germans, found credits in banks which up to that time had been hostile to all industrial investments. New plants emerged from the ground as if by miracle.

Essential Plants Moved From War Zone

One of the electrolytic chlorine plants worked till practically under German shellfire, until the situation became unbearable. The High Command sent a company of engineers who moved cells, engines and boilers and a few weeks later a fine chlorine plant had arisen way down south on the banks of the Rhone.

An oil of vitriol plant was on the firing line. The first and second line trenches went through the build-

*Lecture delivered at the Société de Chimie Industrielle, New York, Nov. 19, 1918.

ings. If the least bit of smoke had come from the stacks, German shells would soon have destroyed buildings and equipment. We were in great need of sulphuric acid. In the dark of the night pine trees were brought down from the Vosges mountains and put into the building to support the roof. Then the plant was dismantled. On moonless nights long lines of trucks took pipes, furnaces, engines and the whole equipment to the rear and when finally the enemy discovered that something abnormal was going on in the plant, their shells crashing through the roof hit nothing but the few dried out pine trees. Some time later this same plant produced in another part of France 15 tons of acid daily.

Many Plants Converted to Munition Work

In the heart of France a peaceful looking flour mill, situated on the idyllic banks of a rivulet, astonished the villagers one day by the strange sight of columns of red smoke escaping through the roof. A new nitration plant had been started.

Elsewhere a mineral oil distillation plant was transformed into a nitration plant. But the people interested there were not satisfied with following the ordinary methods. In my opinion, they built the finest nitration plant in the world. No fumes, no smells, none of the precious liquid lost through leaking pipes or connections. The whole process is performed automatically. On one side the hydrocarbons and the acids flow in a continuous stream into the apparatus and without any human guidance run out on the other side a finished product, ready for packing. Only one attendant is present, who looks after the oiling of the machinery.

Not only was there a shortage of the chemicals, but also of men, equipment, steel, iron and foundries. Often we had to make use of rudimental reactions on account of the scarcity of apparatus we had at our disposal.

Chlorine, which so quickly became an important factor in warfare, was not available, and the same was true of electrolysis plants and manganese salts to produce it.

Though an early end of the war was predicted about every six months, the execution of a far-reaching program was started. It comprised some factories which are going to continue their production in the future.

Before the war the output of the French coal mines was 40 million tons a year; 20 more millions had to be imported. Of that whole production seven-tenths originated from the mines of northern France—a part of which was at the very beginning of the conflict invaded by the Huns. The same happened to the iron industry, of which 87 out of 117 blast-furnaces fell into the hands of the enemy.

Production of Toluol and Benzol

The most up-to-date coke plants were situated in these same regions—at Lens, Liévin, Douai—and their loss was a heavy blow to France. Before 1914 the importation in France of coke byproducts amounted to 80,000 tons and the French output of benzol was 10,000 tons.

It was impossible to increase the production of benzol to such an extent as to meet fully the requirements of the powder plants. New coke ovens were built in the coal region of the St. Étienne; others, working with imported coal, at St. Nazaire for instance, improved their yields of the by-products. The gas plants at Paris, Lyons, Marseilles, Bordeaux and Nantes undertook the washing of gas to extract toluol and benzol, by means of which about 6000 tons of benzol and 2000 tons of toluol were obtained. But as these quantities did not suffice, importations had to make up the balance.

In the line of inorganic products the situation was different. We held the second place for the production of sulphuric acid and phosphates. For instance France's contribution was of 1,000,000 tons of chamber acid. The manufacture of fertilizers, which absorbed 75 per cent of that acid, was stopped and the acid turned over to the munition plants. But this amount was far from sufficient. The St. Gobain Cie., whose largest plant was in territory occupied by the Germans, doubled the size of all its other plants which are located in other parts of France. The Société Kullman of Lille built at Port de Bouc, near the mouth of the Rhone, an entire town, with docks, piers and railroad connections, and erected a lead chamber acid works. Other plants grew up on the Atlantic coast at La Rochelle, St. Nazaire, some of these having a capacity of 200 tons of 66-deg. Baumé acid a day. Last year the total output reached more than 2,000,000 tons of 50-deg. acid.

On the other hand there were but few oil of vitriol factories, to supply which a large number of contact plants were installed. Correct statements of their production has never been published. Thanks to a tremendous increase, importations of sulphuric acid could in 1916 be limited to 100,000 tons.

Manufacture of Nitric Acid

In 1913 France imported 320,000 tons of sodium nitrate from Chile, 90 per cent of which was used in fertilizer. Nitric acid was produced on a small scale, and to get the required equipment a stoneware industry had to be created. Up to that day the Manufacture Nationale de Sévres had produced only artistic porcelains. In a short time they were able to turn out any type of stoneware used in the Valentiners, or for picric acid. Besides, the town of Grenoble has become a center for the making of acid proof metals. From 15,000 tons in 1913, the manufacture of nitric acid went up to 600,000 tons in 1916, and the importation of nitre reached 540,000 tons.

The question of fixation of nitrogen was not as vital as in Germany, but nevertheless attention was paid to it. The first plant was built at La Roche de Ham, in the Pyrénées Mountains, and worked on the principle used in Norway. At Briançon, 7500 tons of cyanamide were made; there, the water power was increased and now 200,000 hp. is available, which will give 100,000 tons of cyanamide a year. Other research work has been made in this line, but no results have been published.

As was the case with nitric acid, the lack of chlorine was a serious problem at the beginning of the war. Several plants working with manganese salts had to be shut down on account of the impossibility of getting raw materials. Other plants were started using chlorate of sodium as an oxidizer. The output of chlorate of sodium was so large that we were able in 1915 to provide our allies with 10,000 tons of it, a marvelous increase over the 1000 tons of 1913. Before the war France did not produce any liquid chlorine. About 20,000 tons a year

are being made at present. At the same time, the production of bromine had developed in France and 500 tons is the yearly output.

In 1913 France had an excess amount of 15,000 tons of caustic soda, which she exported. Now things had changed, this quite respectable production, increased by the new electrolytic chlorine plants, was not sufficient, and she had to import caustic.

Such a large amount of raw materials being now available, the production of war necessities took enormous proportions, and in the hands of our brave soldiers these powerful weapons brought in 1916 and 1917 German militarism to the verge of disaster.

In the region of the Alps a single plant turns out 160 tons of phenol a day and in France in 1916 the production of explosives, not including smokeless powder, was 600 tons a day and reached soon after 800 tons and even 1000 tons a day.

The Dyestuff Industry

At first the French army wore red trousers. Experiments had been made on cloth of dull shade, but when trials were made to apply them it was impossible to get the dyestuffs. The imported tinctorial extracts determined the horizon blue, the color which was adopted for the continental troops. For the colonial army every shade and kind of khaki had to be used.

At the same time the Government started the making of indigo, and as nowadays a perfect method for the manufacture of monochloracetic acid has been found, nearly all the cloth for the army is dyed with indigo. Besides the Government producing indigo, other plants started the manufacture of dyes. In spite of the scarcity of raw material and coal, and especially of apparatus and machinery, the monthly production amounted in 1917 to approximately 250 tons and is now about 400 tons. Two-fifths of these dyestuffs were black.

Among the fifty-odd different shades manufactured in appreciable quantities, a great part are sulphur dyes, but also diazo, basic and fast dyes are now on hand. For the purpose of amalgamating these different efforts and giving them new strength, the Cie. Nationale des Matières Colorantes, under the protection of the French Government, has been founded. This concern has at the present time an entirely paid up capital of 71 million francs. The present complications and difficulties have not prevented the company from undertaking and starting the manufacture of indigo, alizarine and different other anthracene dyes. In accordance with the French character, which endeavors to obtain first of all products of quality, particular attention is given to the manufacture of fast dyes.

The dyestuff industry, being the cornerstone of every other synthetic organic industry, has been backed up to a certain extent and will have to be maintained for a while after the war. Other factories could only continue the production of munitions. For instance, the wood distillation output was increased. Hexamethylene tetramine, which up to the present time had been exclusively an imported article, was manufactured at a plant near Nevers. On the banks of the Rhone another factory was founded for the production of formic and oxalic acid, and in the same part of France aspirin and saccharine were made, restrictions having been strongly modified on the latter product.

Agricultural Products Industry Suffers Drawback

The industry of products connected with agriculture was very prosperous, but suffered a drawback during the war. Let us hope that its importance will soon be regained. Marseilles has two great advantages—first, it is a gate to Africa and the Orient and, second, it is the terminal point of the Rhone valley, which has become of such inestimable value in the chemical industry. The pre-war total production of oils at Marseilles alone was 1000 tons per day and her exportation in soaps was 45,000 tons a year.

The situation at Bordeaux is favorable for the trade with Africa, especially Morocco. This country being unusually rich in wheat and oils, Bordeaux is preparing facilities for the handling of these products and a 300 tons of flour per day mill is operating there.

The supply of tinctorial and tanning extracts was sufficient to permit exportations on a large scale as shown by the statistics of 1913; which is 15,000 tons quebracho and 120,000 tons of chestnut extract. But the appetite of the great war machine was not yet satisfied, and again we see the tireless hands and brains of research chemists working on a new process for synthetical tanning material and the result of their effort is a new industry at Lyons.

Without going into any details, I would like to call your attention to the distillation of rosins, centered at Bordeaux; 10,000 tons of the best turpentine are worth while mentioning.

Neither must I forget to say a word about the industry of essential oils. The sunny climate of the blue shores of the Mediterranean is ideal for the growth of flowers; 5,000,000 lb. of rose leaves, 3,000,000 lb. of jasmine, 1,000,000 lb. of violets and more than half a million pounds of tuberose—that is what the fragrant crop amounted to. And the fair sex of the whole world adds to its charms by using 30 million francs' worth of the precious essences distilled from these flowers.

The overproduction in inorganics may only be apparent. Are not the needs of the soil now greater than ever? Impoverished by four years of insufficient care, we have to make up for this neglect with great quantities of fertilizers. Ours is the wealth in phosphates of Algeria and Tunisia; so are now the potash mines of rewon Alsace, and with these raw materials we shall eat up the 2,000,000 tons sulphuric acid and supply the exhausted countries with fertilizers.

Up to the present time all our efforts tended to destruction. Now the same means which made our war machine so disastrous to the enemy are going to be sources of blessing and wealth to the country.

Phosphorus in Copper Alloys

One grain of low phosphorus alloy and 0.25 gram of high phosphorus alloy such as phosphor copper is dissolved in a mixture of 75 cc. HNO_3, 1.13 sp.gr., and 3-5 cc. conc. HCl. After solution is complete oxidize both HCl and phosphorus by adding $KMnO_4$, 2 or 3 cc. at a time, until MnO_2 separates out. About 15 cc. will be necessary. Do not allow solution to boil down. Reduce MnO_4 by oxalic acid, leaving clear solution, add 10 cc. NH_4OH and 50 cc. molybdate solution. Filter off yellow precipitate and titrate with NaOh and HNO_3.

Notes on Electrical Precipitators

A Summary of Observations Taken From Several Installations — Scope of Process Expanding — Power Consumption, Voltage, Velocity and Temperature of Gases Must Be Experimentally Determined — Types of Rectifiers, Electrodes and Insulators

By ERNEST EDGAR THUM

COTTRELL'S electrical process for precipitating suspended solid particles, condensed fume or vapor from a gas stream is relatively familiar to most readers. It depends upon the fact that when such a gas is passed slowly through an electrical field set up between oppositely charged electrodes the gaseous molecules become ionized and the solid or liquid molecular aggregates acquire an electric charge and receive a directional impulse depending upon the potential gradient of the surrounding field. Thus a small current of electricity passes from electrode to electrode by conductance of the ionized gas and transport of the charged particles. In practice the field is maintained by high-voltage unidirectional current, the negative electrodes consisting of a series of small wires, chains, rods or pipes placed axially in pipes or between parallel metal plates. These pipes or plates are grounded electrodes to which the charged particles largely migrate, and may therefore be called "collecting electrodes." Flues for handling the dirty and clean gas and hoppers for temporarily storing the accumulating precipitate complete the essentials, except for the special electrical equipment for current production and delivery.

The Cottrell process has been a godsend to more industries than to metallurgical plants alone. Early developed as a method to mitigate nuisances and damaging fumes, it was soon found that the deposits had considerable value as by-products.

Greater Sphere of Usefulness

The latest installations as an integral part of manufacturing processes point the way for an even greater sphere of application and usefulness. It is only natural then that the application of even such a relatively simple physical principle to so widely different problems should lead to numberless differences in detail. Indeed, success depends upon many different conditions, and a large number of installations are preceded by painstaking experiments to determine the best way to clear the gases of their impurities. It is extremely difficult to predict the power consumption, voltage, velocity and temperature for correct operation until actual preliminary experimentation has been completed on the gas. The general success of the process is testimony to the excellence of these investigations, as well as to the bulldog grit and determination of the operator, since the latter often encounters most baffling vexations which he is prone to ascribe to the design of his plant. As in all cases, the builder should give much attention to the needs of the men who must make the machine run, and it is hoped that these notes, which apply mostly to the larger installations occurring at smelting plants, may be useful in fixing attention on some important problems confronting designer and operator.

The power house should preferably be quite close alongside the treater, with switchboard and windows so arranged that the electrician can at all times have a clear view of his assistant who operates the knocking mechanism and watches the clearance being effected. The operating platform should be strongly and thoroughly illuminated so that mutual signals may not be interrupted by darkness or foggy weather. Should such a layout be impossible for valid reasons, intercommunication can satisfactorily be maintained only by telephone—receptacles should be installed at a number of points, readily reached by short lines from operator's head-sets. By means of call bells the two partners may thus get into intimate contact without delay. As a safety-first precaution in any case, interlocked colored lights on the circuit-opening switch at each unit should indicate whether the high tension current on the treater is on or off.

It should be borne in mind that the operation of the treater plant will be largely adjusted by the appearance of the exit gases. Indeed, in many cases an excellent recovery of values is effected although the visual clearance is poor; thus a fair visual clearance indicates a satisfactory recovery. Therefore the method is not only simple but effective. In a large installation, one man will continuously be watching the condition of the gases issuing from the treater tubes. Proper illumination should be provided so as to permit easy observation through openings glazed with acid-resistant panes, the illumination extending to all portions of the treater's interior. Observation of the gas as it issues from the tubes is most essential when the effluent is mixed with other smoke before being discharged from the chimney, or when handling hot humid gases which condense a cloud of water particles immediately upon mixing with the colder outside air. Watching the smoke from such chimneys evidently is of limited value. In all cases a series of properly made filtration tests is the last resort to determine the actual efficiency of the electrical precipitator.

For the protection of both the man and the treater the plant should be adequately roofed—if conditions are such that a certain temperature of gas in the treater must be exceeded, as discussed later, it may even be necessary to house it completely during the winter. Conditions which make for the comfort of the operators will in nearly every case inure to the benefit of the plant operations. Thus, in case the draft conditions are such as to require the use of a fan it should generally be placed beyond the treater so that the latter will operate as a "suction" chamber rather than a "pressure" chamber. Should the pressure inside a treater be greater than atmospheric, fume and smoke may blow out through the seams and openings—an ab-

solutely gas-tight job would then be required. Again, after shutting off the gas previous to repairing a treater section, the atmosphere in a suction chamber may be cleared in a few minutes, much more rapidly than if it were under pressure.

Power Equipment

The advantages of sectionalizing a large treater plant are obvious. The same is true of the power house. If each section of the treater is connected to its individual electrical supply, that is, if there is a complete set of motors, transformers, rectifiers, voltage regulators and miscellaneous switchboard accessories to correspond to each division of the precipitation plant, it will be possible to operate each section independently of its neighbors and the electrical conditions in it can be adjusted to secure the best results.

Without attempting a discussion of the special electrical machinery which has provided rugged transformers, low speed alternators, rectifiers and special

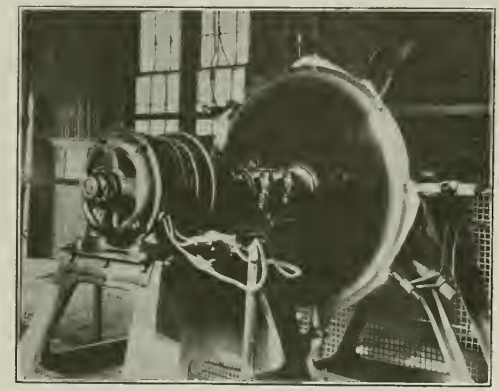

FIG. 1. MECHANICAL RECTIFIER DRIVEN BY SYNCHRONOUS MOTOR

high-tension voltage regulators, it may be said that two methods of current production are in vogue: First, a large alternating current generator of proper rating and design may furnish enough energy for the whole plant, but each treater section will have a separate transformer and its own rectifier driven by a quite small synchronous motor, as shown in Fig. 1. Included in this classification is the case where an industrial circuit of large capacity supplies the transformer-rectifier-treater units. The alternative power house layout shown in Fig. 2 requires a motor, generator and rectifier all on one shaft, the alternating current necessary for the treater unit being generated, transformed and rectified entirely independently of any other unit.

Which of these systems is best is a matter for careful consideration—no dictum should be laid down, since doubtless each has its sphere. Experiments at Anaconda indicate that the wave-form has a determining effect upon the efficiency of the precipitation. Such being the case, commercial current whose characteristics may be suddenly distorted by outside loads should not be rectified. However, this current can be used to drive a single-phase generator especially designed to produce the correct wave-form. Thus it may be that a small motor-generator set working in the second layout may produce a poorer wave-form and more oscillations building up dangerous electromotive forces than a larger machine in the first system, and thus show to poorer advantage. On the other hand in units of large capacity, operating troubles in one section may modify the current delivered to all others from the central generator, so that the latter scheme would then be more satisfactory.

While the first-mentioned power plant is somewhat simpler, it can be installed but little more cheaply than the second when proper induction voltage regulators are included. At most, the electrical equipment costs but 15 per cent of the total, and it is false economy to install unsuitable machinery, since in this case the yearly repairs and renewals may mount to one-quarter the first cost, and unsatisfactory operation cause the whole to be discarded after a short life. Operation demonstrates that precipitating conditions in each treater-unit may vary so much as to require individual electrical control —indeed, ideal conditions are reached when the voltage existing on each discharge electrode can be adjusted.

Spare armatures, of course, will be provided; but a spare transformer is often neglected, although it is nearly as essential. Horn gaps may be used to assist in protecting the transformer insulation, set slightly further apart than the radius of the treater pipes. Ample precautions should be taken to protect all transformers, rectifiers and other equipment. Permanent series resistances in both high and low tension lines are effective in interrupting oscillating discharges and limiting short circuits. Condensers shunted across the generator leads are also useful in absorbing surges reflected from the transformer windings. Adequate lightning and switchboard protection will be suggested by the electrical designer as a matter of course.

It is well to have all the electrical machinery of large capacity. In this relation, the preliminary investigations should determine particularly the electrical characteristics of the precipitated material, since it has been shown that the resistance of the gap between clean

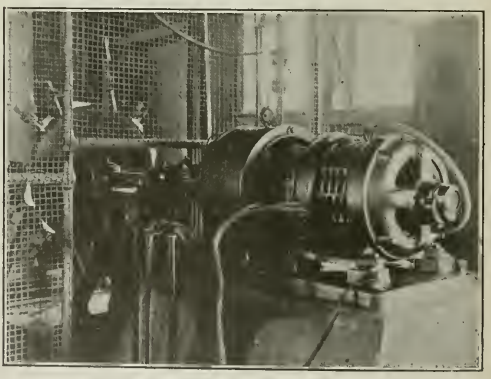

FIG. 2. MOTOR DRIVING A SINGLE-PHASE GENERATOR AND MECHANICAL RECTIFIER

discharging and collecting electrodes may be lowered as much as 50 per cent by a thin non-conducting deposit. The voltage on the system must then be lowered in order that heavy arcs may not trip the circuit breakers. Such discontinuous dielectrics retain their electrical charges

and ionize the surrounding gases if the dielectric constant of the particles be large. The remedy is to make the deposit conductive by humidifying the gas or (in case corrosion is feared) by adding a conducting dust like carbon.

Obviously large voltage regulation may best be had by changing the tap into the low-tension side of the transformer, and close regulation within these steps by adjusting the voltage produced by the alternating current generator. The wave form of the rectified current and to a less extent its voltage is adjusted by rotating the rectifier "brushes" slightly.

Current Characteristics

In order that this may be clear to those who are not well acquainted with such installations, it may be well to diagram an early rectifier quite good for low voltages. This consists of two conducting arms set at 90 deg., insulated from each other and the shaft which drives them. The brushes (which are merely short lengths of trolley wire suitably held in insulated clamps with ends about ¼ inch from the edges of the rotating segments) are also at quadrant points, and are connected as shown in Fig. 3. At the instant sketched the transformer may be assumed to be giving its maximum negative potential to *b* and *c*, while *z* and *w* are correspondingly positively electrified. The positive electricity jumps the short air gap at *w*, travels through arm *v*, across the gap *y* and thence to earth. Similarly a negative current is delivered through brush *b*, arm *a*, brush *d*, and line to the wire electrode. In the treater itself the circuit is completed from charged wire to grounded pipe through the ionized gas.

Fig. 4 is a sketch and Fig. 5 a photograph of the rectifier now commonly used. It consists of a synchronously rotating disk of non-conducting fiber or composition to the edge of which is riveted the metallic

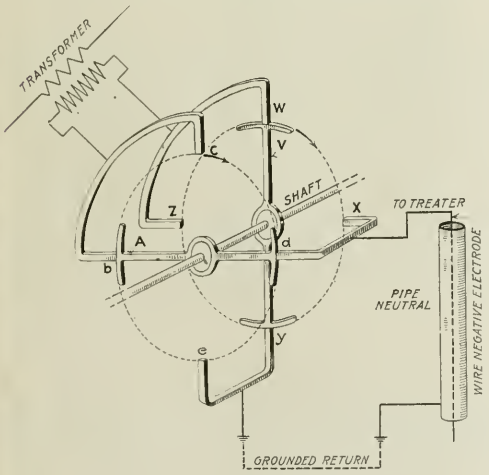

FIG. 3. EARLY RECTIFIER FOR LOW VOLTAGES

quadrants *A* and *V*. Brushes *b*, *d*, *y* and *z* are metallic horns symmetrically fixed in a movable frame. Its operation is quite similar to the older style, and can be easily traced in the light of the following discussion.

Referring again to Fig. 3, the rotation of the arms *A* and *V* interrupts the circuit when the moving end of the segment draws the arc out to a breaking point; meantime the voltage delivered by the transformer is decreasing and by the time the shaft has rotated a quarter-turn the current has reached its opposite maximum. Arm *A* will then be opposite brush *c*, delivering its charge (then positive) to ground through *e*, while arm *V* will deliver another negative impulse from brush *z* to the treater through brush *x*.

In this manner unidirectional, intermittent current is sent to the wire electrodes in the precipitation plant. Reference to Fig. 6 will give the characteristics of the current sent to the treater, where the wave is the

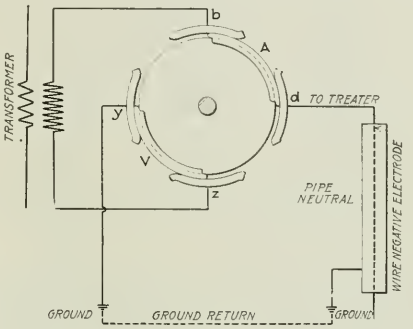

FIG. 4. WIRING DIAGRAM FOR MECHANICAL RECTIFIER FOR HIGH VOLTAGES

ordinary sine curve representing the time-voltage relations of an ideal alternating current. Arm *A* collects the troughs of the waves during a time on each side of the minima shown by dark portions of the curve, while the peaks are collected a half-period later by arm *V*. If all eight brushes are attached to a frame capable of being rotated around the shaft, it is easily seen that turning this frame counter-clockwise will collect the current at an earlier time on the increasing voltage wave. Fig. 7 shows the portion collected in darkened lines as before, and it is plain that each impulse starts at a relatively low voltage, rapidly increasing to the maximum, when it is interrupted. On the other hand, clockwise rotation will first catch the current nearer its crest voltage and deliver an impulse of rapidly decreasing potential (see Fig. 8).

In adjusting the treater clearance it is common for the electrician to throw the brush holder to one limit of its travel, and then move it slowly back and forth until his assistant watching the clearance signals the best location. Then the appearance of the arcing of the rectifier or the reading of a milliammeter on the high tension line is relied upon to exhibit variation in electrical conditions in the treater. Naturally "fine-haired" adjustment of these brushes is not essential, since changing conditions in the treaters demand attention from the operatives at intervals. Synchronism between the alternating current and rectifier is of prime importance, however—this synchronism is evidently absolute when generator and rectifier are keyed to the same shaft.

Since the part of the current wave propelled toward the treater depends upon the potential of the crest, the

width of the air gap and the length of the brushes (as well as the angular setting of the latter), it is evident that the adjustment of the position of brushes such as sketched in Fig. 4 will greatly alter the characteristics of the sparking at the rectifier. The peak only may be collected, resulting in short snappy arcs at the rectifier, or long flaming arcs may almost envelop the circumference of the disk when commutating long portions of

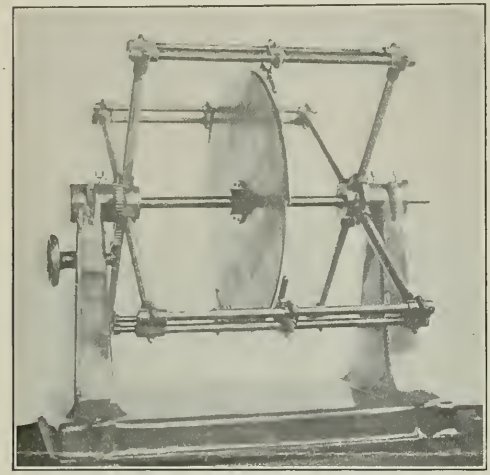

FIG. 5. MODERN RECTIFIER

the wave. The latter obviously transmits a greater amount of energy into the treater.

Constant tampering with the brushes is not conducive to best operation, for if other things are equal the efficiency of precipitation will vary as the impressed voltage. It is therefore essential that the power house deliver uniformly a potential closely approximating that which produces arcing in the treater tubes. The potential wave actually existing across the electrodes is very flat, quite different from that existing at the brushes, since the treater acts like a condenser, and discharges very slowly by transport of charged particles.

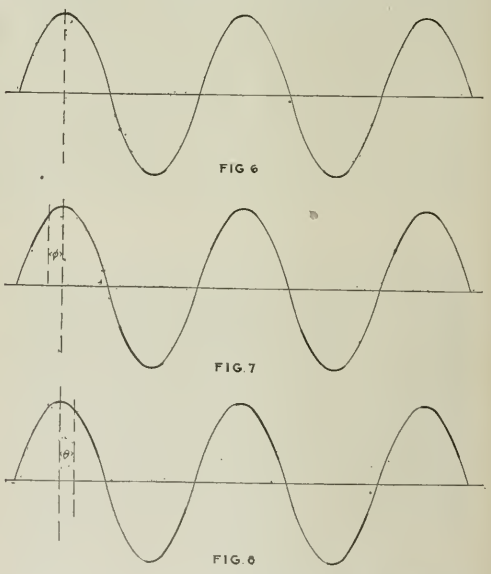
Electrodes and Insulators

Treater construction has been standardized to the extent that the smelter smoke to be cleaned usually flows from a hopper to a collecting flue through upright pipes or between parallel sheets. This whole structure is grounded. The negative current is distributed to wires, chains or thin pipes, stretched by weights or springs through these collectors and accurately centered at both ends by latticed frames. These frames in turn are supported by cross-beams extending through openings in the hopper and flue walls, there resting on proper insulators and protected from accidental contact by a basket or "pent-house." However, it is not desirable to depend upon air seepage to keep the dust from gradually settling on the insulator, especially in case the gas carries free sulphuric acid (as do copper converter and roaster gases).

In the latter case a treater designed to catch dry dust must operate at a temperature above that of any considerable condensation of the free acid, and any infiltering cold air would speedily deposit a tenacious acidic film upon the insulator, causing grounds and punctured insulator petticoats. In such cases it has been found desirable to frame a beam into the ends of those supporting the latticed frames, which beam will extend longitudinally outside the flue walls. This longitudinal beam is then supported by insulators placed centrally some distance from the openings. The whole is enclosed by an iron box, preferably welded air tight at all joints, with weather-stripped doors of glass opposite each insulator, all as shown in sectional plan in Fig. 9. An excellent precaution is to have the levers controlling the high tension tower switch so arranged as to extend in front of these doors when the current is on. In order to get into the insulator box it is then necessary for the attendant to move the switch levers, thus cutting off the current before being able to open the door.

Replacing Punctured Insulators

A large item of upkeep is for replacing punctured insulators, so that careful testing is necessary to get a suitable type. Often it may prove that an inexpensive insulator lasting but a relatively short time will be more economical than a costly one of little longer life. Satisfactory home made insulators are in use on moderate voltages consisting merely of a pile of porcelain slabs, about ¾ inch thick and 6 inches square, alternating with acid-proof tile, of the same thickness and about 3½ inches square. It is hoped that research now under way may develop a new type of insulator which will stand up in warm, dusty and acid-laden atmospheres.



FIGS. 6 TO 8

Fig. 6. When brushes are set at theoretical point of maximum voltage.
Fig. 7. When brushes are rotated counter-clockwise through an angle ϕ
Fig. 8. When brushes are rotated clockwise through an angle θ from theoretical position

The collecting tubes or plates of course should be quite clean and smooth so that no electrical leakage at shortened air gaps may occur. In some installations cor-

rugated iron has been found to be a good material with which to build collecting plates. In tube treaters, it would evidently be good policy to expand the ends of the tube into a pronounced bell before joining into the top and bottom sheets to reduce electrical leakage at the ends.

However, as precipitation proceeds a fume deposit builds up on both pipe and wire, facilitating point-discharges and decreasing the air gap as well. In order to restore the tubes to their normal condition it is necessary to shake this dust free at intervals. Machanical rapping may be done by hammers hung from an oscillating horizontal shaft between alternate rows of pipes striking on welded pads, and a similar hammer striking compression springs fixed on the latticed frames supporting the electrodes. The current of electricity must evidently be interrupted during shaking of the charged electrodes and is usually stopped when

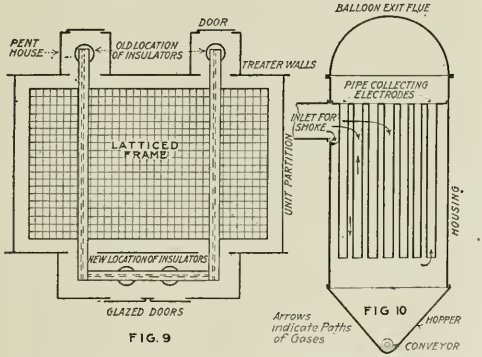


FIG. 9. METHOD OF PLACING INSULATORS DISTANT FROM OPENINGS INTO BODY OF TREATER. FIG. 10. SKETCH OF TOP INLET FOR UNIFORM GAS DISTRIBUTION

rapping the collecting electrodes, but in any case the jarring mechanism should be grounded in two independent ways. In passing, it might be stated that the whole grounded structure should be connected thoroughly and carefully to a return wire. A little trouble and expense here will save foundation piers split by corroding anchor bolts, electrolysis of water mains, and perhaps life itself. All rapping is best done by power, since mechanical operation is independent of human fatigue, and is therefore more efficient and expeditious. The equipment, especially ball cranks and bearings, should be more than amply strong to endure satisfactorily the severe alternating stresses without frequent and vexatious breakages.

Interruption of Gas Current

Whether the gas current should be interrupted during shaking depends largely upon conditions. In large sectionalized installations the provision of one complete unit in precipitator and power plant is desirable. With such a layout one unit may be regarded as a spare and may be continually out of service for cleaning or for repair of any integral part without interfering with the proper operation of the plant. With all units operating, an ample margin for good performance is furnished. If, however, the entire treater plant is working near its capacity, shutting the gas from the unit being shaken will only overload the others, and some loss in clearance and values will ensue. In such cases it would probably be well to rap the plates or tubes at short intervals without interrupting the gas or current, cutting off the electricity only when rapping the charged electrodes at longer intervals. In the case of inflammable or explosive fume it is essential that the treater be large enough that both the gas and electricity may be interrupted during shaking, so sparking may not cause disastrous fires.

The snapping discharge of spark-overs can be heard by the treater tender or located by looking into the upper flue or lower hopper. If a thorough rapping of electrodes will not stop the trouble or if a localized arcing discharge is robbing the bulk of the tubes of their supply of electricity, it may be necessary to shut down the section, and remove the cause. Should this be the presence of dust accumulations, it will be necessary to clean thoroughly each tube by raising and lowering a weighted, special boiler-tube cleaner. Fortunately the dust is strongly adherent only in rare cases—for such it may be necessary to build the balloon flue high enough so that the weighted electrodes may be taken out of the pipes by bodily raising the supporting grid by chain blocks, when a scale-cutter operated by a motor driven flexible shaft can be thrust through each pipe in succession. Such heroic and disagreeable alternatives might be obviated by changing the characteristics of the deposit by proper additions to the entering smoke.

After the electrodes are properly cleaned, centered and weighted, operations should approach normal. Snappy spark-overs do not affect the treater operation seriously, since they consume but little power, and the generating system and transformer are protected from the effect of the momentary short circuit by the rectifier. As is seen from an examination of Figs. 6, 7 and 8, at each half-cycle there is a complete separation between the alternating current supplied to the rectifier and the unidirectional current delivered by it. For 60-cycle current most of these line disturbances are therefore cleared in much less than 1/120 part of a second. Localized arcing is more rare, and is instantly recognized by a jumping ammeter needle and heavy flames at the rectifier. Such arcs should open circuit breakers before damage is done, or can be made to introduce a protective resistance in the low-tension circuit automatically.

Fortunately wire electrodes are seldom burned off or fused, owing to the relatively low amperage of the spark-overs. Considerable difficulty has been experienced, however, in a case where the weighted electrode wires were centered by small holes through the lower grid. Variable resistances at the top caused considerable current to be fed through the bottom spacer—this recurring and localized spark burned off many wires, dropping the weights and shutting down the unit. This trouble has caused the adoption of springs for giving the required tension, but their failure through rapid annealing at elevated temperatures suggests that a more rational solution would have been to have the lower grids carry stirrups which would center a sash-weight of such considerable diameter that its fusion would be impossible.

A thin non-conducting deposit, a thick conducting

deposit or a derangement of electrode spacing may reduce the treater voltage, as already noted. In addition to this, leakage over wet or defective insulators may be very hard to locate and cause serious trouble. Again, at more than 50,000 volts stretched wire electrodes tend to vibrate in elliptical orbits on account of unbalanced attractive forces being suddenly relieved by a local arcing discharge. (Damping rods or the use of chain electrodes cures this tendency—very high voltages may require rigid electrodes.) A further cause of lowered voltage is the screening of the discharge due to a high concentration of dust or fume in the gas. Should the polarity of the charged electrodes become reversed through any cause, a corona discharge will occur at a fraction of the negative potential.

Since the efficiency of the precipitation depends upon the maintenance of the maximum voltage in the treater, constant attention to all such points is required of the careful operator.

Gas Distribution and Temperatures

Properly made experiments preliminary to construction will determine the best conditions of voltage, pipe lengths and diameter for all normal variations in temperature, composition and velocity of the gases. It is not so easy to translate the results attained with one or a few pipes to an installation containing hundreds. Perhaps the most trying thing is the attempt to insure equal gas distribution to all of the dozens of pipes in one section, especially with the low velocities desirable.

If the main intake is merely a pipe opening into the side of the dust collecting hopper, it is evident that there may be large differences in pressure in the collectors with their varying distances from the intake. In some cases the gases are discharged through a ventilator-like hood set in the center of the hopper. Then the corner and middle pipes may suffer. The difficulty of operating a rotating gas distributor in a dust-laden, acid atmosphere can well be imagined. The design should be such as to prevent eddies as far as possible. Evidently nearly ideal gas distribution could be provided in a vertical-pipe treater if set directly above a furnace outlet, connection between the two being made by a straight, uniformly tapering flue. Or, in their passage through a long, straight flue of ordinary construction, if the gases should pass through a section containing vertical sheets and horizontal electrodes placed parallel to the flue walls, they would suffer the minimum derangement in pressure, direction and velocity while going through these narrow passages.

Many peculiar installations may be ascribed to the fact that the precipitator was added to an operating plant where scant opportunity for a correct layout existed. Where head-room is lacking or a tall structure seems undesirable, a distribution as good as any attainable after a sharp turn may be had by introducing the gas near the top of the housing around the collecting electrodes, as sketched in Fig. 10.

Even with the most perfect mechanical design, however, furnace operations vary enough to make large differences in temperature, volume and composition of the gas to be handled. If differential precipitation is to be attempted, close temperature control will be essential so that only the desired volatiles may be condensed. In this case, the treater pipes may be surrounded with adjustable louvers, so that cold air can be excluded or admitted, as the case may be. At the other extreme, it may be necessary to keep up the temperature of the entering gases by previous admixture of hot furnace gases from another source. Fume-laden gases are often cooled, and at the same time their electrical conductivity and efficiency of the precipitation bettered, by water sprays discharging into the flue leading to the precipitating plant. This last method must be used with circumspection, however, if acids are liable to be formed and collected in the precipitator.

Large temperature variations have another profound effect on treater operation besides the fact that a rise in temperature lowers the arcing voltage, which is that it causes large differences in the volume of gas to be treated, and consequently its velocity through the treater. A particle of fume starting up the precipitator wanders about in an indefinite manner until it acquires an electrical charge, when it is impelled to one electrode or the other at a comparatively rapid rate. If the particle is to be caught, the original vertical velocity must not carry it out of the electrical field before it becomes electrified. Recognizing this fact, a careful designer would be justified in adding perhaps 20 per cent to the pipe length which experiments show to be about right, to take care of the unusual velocities which are sure to appear.

Certain operations may produce a fiendish smoke which will not only corrode the metal about the treater but will also precipitate an inflammable (not to say explosive) fume. Fume from Dwight-Lloyd roasters making sinter for lead furnaces, for instance, is highly combustible when the elemental sulphur runs above 25 per cent. (For such plants, adequate fire protection, such as hose, plugs and accessories, should be instantly available.) Walls of acid-proof brick construction would be badly shaken by a flare even after ample explosion doors had blown open. Such conditions have been successfully met by lining a steel skeleton with Johns-Manville "transite board," a type of asbestos lumber which is not only acid proof but is an excellent heat insulator as well.

Combustible dust should evidently be removed from the neighborhood of the electrical discharges as rapidly as collected. Screw or drag conveyors are available for this service, but they should be made several times as strong as the designer ordinarily thinks is necessary so that they may break up and remove the wet, caked dust remaining after a fire has been extinguished without themselves breaking.

Ramsay Memorial Fund in America

It is the desire of the American Committee of the Ramsay Memorial Fund to make the fund an expression of the esteem for Sir William Ramsay in this country. Many have expressed a wish to contribute, but have held back on account of their inability to send in a sum commensurate with their esteem. This has been due to the numerous calls made upon all for the past two years. Small sums, from one to five dollars, will be welcomed by the Committee, which is anxious to make the expression of appreciation as widespread as possible. Contributions may be sent to Prof. Charles Baskerville, Chairman, College of the City of New York, or Mr. W. J. Matheson, Treasurer, 21 Burling Slip, New York City.

Furnace Settings for Caustic Pots

Designs of Radial, Tangential and Reversible Series Dutch Oven Type Furnace Settings for Counter Current Economizer Caustic Soda Pots—The Development of the Most Efficient Modern Types

By FRANK H. NICKLE

In the early furnace settings, adapted for firing caustic pots with coal, the pots were suspended by means of a wide flange at the rim, or a cast iron saddle ring, the weight of the pot in either case being carried by the surrounding brickwork. The grates were placed directly under the pot, thereby subjecting the bottom of the pot to the most intense heat. As larger pots came into use, it became desirable to support the pot on a central pier, thereby relieving the surrounding brickwork of the load and also protecting the lower extremities of the pot from an excess of heat, which had a tendency to interfere with the proper settling of the foreign matter in suspension in the caustic liquor.

An early design of a caustic pot setting is shown in Fig. 1, which is reproduced from the well known works of Lunge. The grates are placed adjacent to the central supporting pier, and within the confines of the brick wall that surrounds the pot. The furnace gases divide on the center line of the combustion chamber and travel 180 degrees in opposite directions around the pot.

The usual practice in this country has been along similar lines, with the addition of a Dutch oven to accommodate longer grates. The Dutch oven is built on the center line of the pot, so as to deliver the products of combustion radially toward the pot, the gases dividing on the center line and traveling in opposite directions around the pot to a common flue connection in the rear. To designate this type of construction, from the writer's improved designs, the same is termed the "radial Dutch oven type."

This radial Dutch oven type, Fig. 2, is illustrated by a battery of two direct-fired pots operating in conjunction with a third or back pot, the back pot serving as an economizer or preheater for the recovery of waste heat from the flue gases. To prevent the direct impingement of the flame upon the pot, a V-shaped vertical fire guard or segmental apron is placed directly in front of the pot. The introduction of this fire guard, although affording a measure of protection to the pot, leads to other difficulties. It restricts the throats at the entrance of the heating passages. In some cases the area of these openings is only fifteen or twenty per cent of the grate surface. If these throats are made amply large, then the support of the rear end of the arch over the combustion chamber becomes a delicate matter, as the diverging walls do not afford suitable skewbacks at the spring line. This makes it necessary to corbel out the rear end of the arch toward the pot in a V-shaped manner, in order to provide a support for the circular brick wall that surrounds the pot directly above the combustion chamber. In this overloaded and weakened condition, the rear end of the arch is called upon to withstand the most intense heat, due to the direct impingement of the high velocity furnace gases and the radiant heat reflected from the fire guard.

The back pot, which serves as an economizer for both primary pots, is usually elevated so that a portion of the liquid contents may flow by gravity to the front pots. As illustrated in the plan view, the flue connection between the front and back pots is sometimes made as short as possible by locating the same on a center line drawn through the front and back pots. This reduces the floor space occupied by the pots; however, the fallacy is obvious. The travel of the heating gases,

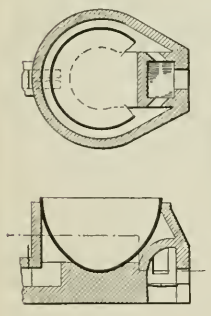

FIG. 1

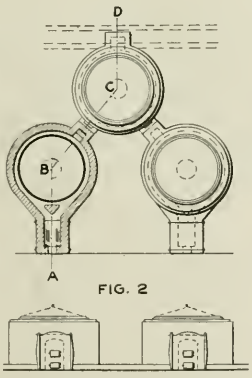

FIG. 2

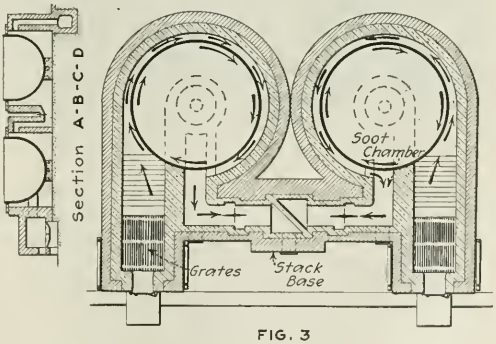

FIG. 3

FIG. 1. EARLY DESIGN OF CAUSTIC POT SETTING. FIG. 2. RADIAL DESIGN OF CAUSTIC POT SETTING. FIG. 3. NICKLE TANGENTIAL DUTCH OVEN TYPE.

in active contact with the front pot, is reduced on one side and increased a like amount on the opposite. This unequal length of travel, about 140 and 220 degrees respectively, naturally causes the heating gases to short circuit and follow the shorter course. Consequently, only one side of the pot, adjacent to the shorter heating passage, is worked to capacity, the volume and velocity of the heating gases being deficient on the opposite side. This unequal distribution of the gases results in a poor natural circulation of the liquor undergoing concentration, also a low rate of heat transmission and

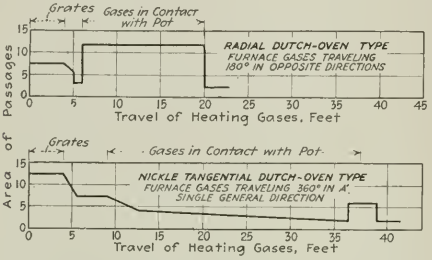

FIG. 4. RELATIVE AREA OF PASSAGES AND TRAVEL OF HEATING GASES.

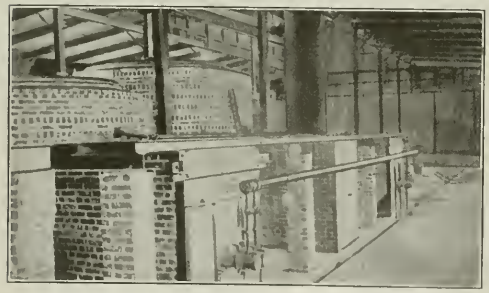
high temperature flue gases, which makes the use of a back pot more or less imperative. The back pot setting, as illustrated, is subject to the same criticism, with respect to the unequal distribution of the heating gases, especially so when the firing of either of the front pots is curtailed.

Tangential Dutch Oven Type

One of the writer's improved types of furnace settings for caustic pots is shown in sectional plan in Fig. 3. This design, hereinafter termed the "tangential



A GAS FIRED FURNACE SETTING FOR CAUSTIC POTS.

Dutch oven type," consists of a battery of two pots, each being heated by means of a Dutch oven adapted to deliver the products of combustion tangentially to one side of the pot, the heating gases traveling substantially 360 degrees around the pot in a single general direction. At the end of the circumferential travel, adjacent to the combustion chamber, is a soot chamber with a clean-out door. A small sheet iron stack serves each battery, the stack base being located midway between the Dutch ovens.

The usual fire guard construction, to protect the pot from local overheating, is omitted. This leaves the throat back of the bridge wall unrestricted. The area of the passage, where the furnace gases first come in contact with the heating surface, may be conveniently

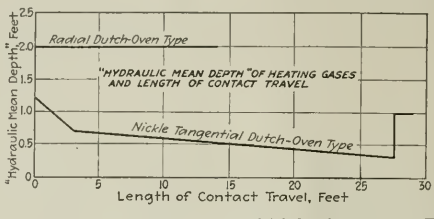


FIG. 5. CHART SHOWING DIFFERENCE BETWEEN THE TWO TYPES.

made equal to 50 per cent of the grate area. This large passage insures a uniform distribution of the gases over a relatively large area of heating surface. It reduces the initial velocity of the highly heated gases and eliminates the blowpipe effect. This desirable feature, together with the tangential application of the gases to the curved surface of the pot, prevents overheating at the initial point of contact.

As the rate of heat transmission is largely dependent upon the velocity of the heating gases, the area of the heating passage is gradually reduced until the end of the circumferential travel is reached. This offsets the

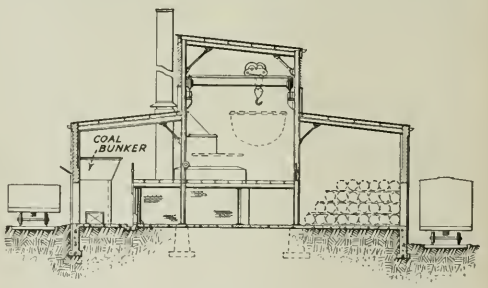

FIG. 6. SHORT SPAN BUILDING FOR CAUSTIC POT FURNACES.

reduction in volume of the gases due to cooling, increases the velocity and favors the effectiveness of the heating surface near the end of the travel. The relatively low velocity of the gases leaving the combustion chamber tends to prevent the entrainment of ashes and cinders from the fuel bed. Accelerating the velocity of the gases lessens the soot deposits in the heating passage and permits the deposition of the soot in the soot chamber, where the velocity is suddenly retarded.

"Hydraulic Mean Depths" Considered

The impartation of heat to a caustic pot is largely by convection, as very little heating effect is derived by radiation from the surrounding brickwork when the brick surface becomes sooted. Consequently, we may say that the rate of heat absorption, by the dry wall of a caustic pot, is largely determined by the length of the gas contact travel and the "hydraulic mean depth" or the average mean distances of the particles of gas from the heating surface.

Comparing the radial and tangential Dutch oven designs, see Fig. 4, the first condition, the length of the gas contact travel, is readily seen to be substantially doubled in the tangential Dutch oven type.

The second condition is not so easily apprehended. The "hydraulic mean depth" is the quotient of the area of the cross section of the gas stream divided by the perimeter formed by the heating surface of the pot touched by the gases. This may be expressed by saying that the closer the gas particles are directed to the pot surface, the more contacts they can make with it in a unit of time. In other words, the "hydraulic mean depth" should be made as small as the draft conditions will permit.

The "hydraulic mean depths" for the two designs under consideration are shown graphically, at any point of travel along the heating passages, in Fig. 5. In each case the gassed perimeter is constant and may be taken as 6.0 feet. The "hydraulic mean depth" for the radial Dutch oven design is 2.00, and may be illustrated by a straight horizontal line, as the flue area is constant. For the tangential Dutch oven design, the "hydraulic mean depth" varies from 1.25 at the initial point of contact to 0.33 at the entrance of the soot chamber, the average being about 0.75.

Advantage of the Tangential Dutch Oven Type

A comparison of the average "hydraulic mean depths" for the two designs clearly illustrates the advantage of the tangential Dutch oven type. It indicates that the gases will make an average of 2.66 times as many contacts with the heating surface in a unit of time. To arrive at this comparison, the volume and temperature of the heating gases leaving the combustion chamber must be the same in each case, allowance being made, in the radial Dutch oven design, for the fact that there are two streams of gases.

Lack of adequate circulation in a caustic pot is also a check to efficient heat transmission. If there is no circulation, the liquor undergoing concentration, or heat treatment, abstracts heat from the pot wall by conduction, which implies no mechanical motion between the contact surfaces of the two bodies. All liquids at rest absorb heat by conduction very slowly. Likewise, a layer of steam bubbles on the heating surface, unless in motion, act the same as a dry gas, the conducting power of which is inappreciable.

The rate of heat transfer, from the pot wall to the liquor, is largely dependent upon the contact velocity of the liquor. There must be an interchange of position between the hotter and the colder particles of liquor in order to permit the heat to flow by convection. The liberation of the steam bubbles is the impelling force that largely effects the desired circulation.

The question now naturally arises—how can the circulation of the liquor in a caustic pot be increased without resorting to mechanical means? The logical answer is, to apply the heating gases to the exterior of the pot in a manner that will promote the rotation of the liquor in a horizontal direction about the axis of the pot. In the tangential Dutch oven type of pot setting, the natural circulation of the liquor is in a horizontal direction concurrent with the circumferential travel of the heating gases, as set forth in the writer's U. S. Patent No. 1,191,338, from which the following typical claim is quoted:

"In a furnace setting for caustic pots, the combination of a furnace, a caustic pot having liquor therein, means to cause the liquor to rotate, said means being the products of combustion applied tangentially to the exterior of the pot and traveling in a direction concurrent with the rotation of the liquor within the pot."

In causing the liquor to rotate in a substantially horizontal direction about the pot axis as a center of rotation, the only resistance encountered is the skin friction between the liquor and the pot wall, the scouring action of which is desirable, as it tends to rub the steam bubbles off the heating surface and promote better contact therewith.

Rotating the liquid contents of a caustic pot not only facilitates the abstraction of heat from the pot wall; it causes the foreign matter in suspension to float toward the center of rotation and settle down out of the zone of active circulation. It thus saves time in settling the highly concentrated or molten caustic soda, improves the appearance of the solid product, and reduces the amount of caustic bottoms to a minimum.

This tangential Dutch oven type of caustic pot setting was first installed, under the direction of the writer, during 1913, by the Dow Chemical Co. at Mid-

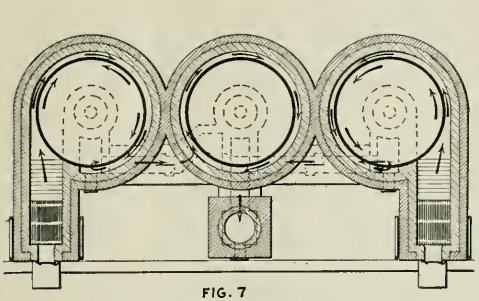

FIG. 7

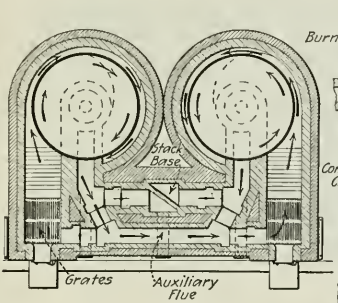

FIG. 8

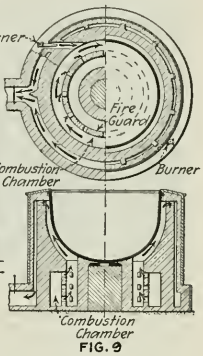

FIG. 9

FIG. 7. NICKLE TANGENTIAL DUTCH OVEN TYPE WITH ECONOMIZER POT. FIG. 8. NICKLE REVERSIBLE SERIES TANGENTIAL DUTCH OVEN TYPE. FIG. 9. NICKLE GAS FIRED TYPE.

land, Mich. The initial installation consisted of four furnaces, which have been subsequently increased to a total of twenty-two. The fire brick arches over the Dutch ovens on the initial furnaces were renewed for the first time during the latter part of 1918, after having been in continuous service for a period of nearly five years. The successful operation of these furnaces has demonstrated the correctness of the principles involved in the tangential application of the heating gases to the pot in a single general direction. Without any economizer or back pot, these furnaces have proved

NICKLE TANGENTIAL DUTCH OVEN IN PROCESS OF CONSTRUCTION.

quite as economical in fuel consumption as the radial Dutch oven type with the usual third or back pot.

Omitting the third or back pot means a saving of about one-third of the investment. Aside from saving the expense of the back pot and the brick setting for the same, it involves a substantial reduction in building costs, as the tangential Dutch oven type is adapted for short span building construction. The general arrangement of a short span caustic shed is shown in cross-sectional elevation in Fig. 6. In this design, the floor space served by the traveling crane is reduced nearly one-half, as compared with the usual layout that accommodates the radial Dutch oven type employing back pots.

As shown in Fig. 7, a battery of two tangentially fired pots may be operated in series with an economizer or third pot. In this arrangement, the flue gases from both of the primary pots travel 360 degrees circumferentially in a single direction around the middle pot. An installation of this type, fired with natural gas, at the plant of the Warner-Klipstein Chemical Co., Charleston, W. Va., leads the writer to believe that the economy that may be effected by the third pot will not justify the extra investment under the average conditions.

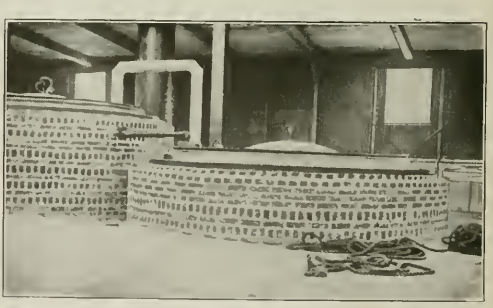
A better way to recover waste heat from the flue gases, without resorting to the use of a third pot, is shown in Fig. 8. This design is the same as the tangentially fired two-pot battery shown in Fig. 3, with the addition of an auxiliary flue and the necessary dampers to enable the operation of the furnaces in reversible series or parallel. When operating in series, either pot may be fired as a primary, while the other serves as a secondary for preheating and effecting the initial concentration of the fresh caustic liquor by means of waste flue gases from the primary pot. A reversal of the dampers converts the secondary pot into a primary and vice versa. The evaporation in the secondary pot may be increased by firing the same lightly to augment the heating effect of the flue gases from the primary setting, otherwise, if desirable, the fire in the secondary Dutch oven may be banked.

Another New Type

Another new type of furnace setting, adapted for caustic pots and various kinds of retorts, is shown in Fig. 9. The following extracts from the writer's pending patent application will suffice for description:

This furnace setting is designed especially for firing caustic pots or other containers with crude oil or gas. An annular combustion chamber, located below the pot and concentric therewith, is made to deliver the products of combustion through a plurality of radial ducts spaced circumferentially in a fire guard that surrounds the circular pier upon which the pot rests. The combustible is supplied by hydro-carbon burners arranged to deliver the blast tangentially to the exterior of the fire guard and in the same general direction of rotation. The radial ducts in the fire guard being at right angles to the direction of the blast, it is evident that the burning gases are caused to travel a considerable distance before gaining entrance to the heating passage at the bottom of the pot.

The endless travel and swirling motion assure a thorough mixing of the burning gases, while the same are being intensely heated by the radiant heat from the wall that surrounds the combustion chamber. This insures good combustion before the gases are subjected to the chilling effect of the comparatively cold heating surface of the pot. The distribution of the gases is uniform around the pot supporting pier, the travel being upward while in contact with the heating surface. This uniform distribution of the gases, without direct impingement of the flame upon the pot, favors the life of the pot. There is no occasion to turn the



COMPLETED INSTALLATION OF NICKLE TANGENTIAL DUTCH OVEN.

pot at intervals to distribute the wear, as is the custom when other types of furnace settings are employed.

Another characteristic peculiar to this type of furnace setting is the use of the waste flue gases for heating the exterior of the fire wall that surrounds the combustion chamber and the pot, the object being to reduce heat losses therefrom by a reduction in the temperature range between the inner and outer faces of the fire wall. An outer wall, concentrically spaced from the fire wall and joined thereto at regular intervals with radial slip-joints, forms a plurality of downtake passages circum-

ferentially arranged and adapted to withdraw the flue gases from the top of the heating passage that surrounds the pot. This construction also provides for a differential rate of expansion and contraction between the inner and outer fire brick walls.

The use of this type of furnace construction is not confined to caustic pots. About thirty furnaces of this type have been installed for the manufacture of carbon bisulphide.

Saginaw, W. S., Mich.

Platinum Economy in the Industrial Chemical Laboratory

By E. C. Mueser

THE present high price of platinum and recently the real difficulty of obtaining this metal due to Government restrictions in behalf of its conservation for essential war industries, among which were its use in sulphuric acid plants for concentrating pans, its use as contact metal, as catalyzer and other uses, have made it necessary to conserve carefully the analytical laboratory supply of platinum ware. In many laboratories, in order to avoid great expense in replacing this ware and inconvenience due to its shortage caused by difficulty in obtaining new platinum, it was found necessary to make a careful study of the economy of the platinum-ware equipment of the laboratory.

Aside from the importance of conserving platinum ware to avoid analytical inconveniences caused by difficulty in replacing, the platinum of the average laboratory represents a considerable percentage of the total equipment investment, and its rapid deterioration, due to careless or ignorant use, adds very materially to the maintenance and operating costs of the laboratory. In view of these considerations it seems timely to call attention to some basic principles for the proper use of platinum in the chemical laboratory. The first step in conserving platinum ware is, of course, restriction of its use to operations where it is absolutely necessary, that is, where laboratory apparatus, such as crucibles, of iron, nickel, nichrome, alundum or platinum "substitutes" cannot be used because of the nature of the material and the nature of the operation. When platinum ware must be used a careful attention to its proper use will double or triple the life of platinum crucibles and other platinum ware in the laboratory.

The proper care of platinum ware is a matter to which many laboratories have not given the attention demanded by the large investment it represents. In many laboratories platinum ware is frequently ruined through the analyst's carelessness and through ignorance of unskilled routine workers. The proper use of platinum ware should be carefully prescribed in all laboratories and should be restricted to its necessary uses, instead of permitting its use whenever convenient. Some of the platinum substitutes, which, however, are also high priced, may be recommended, and the laboratory chief will find these suited to much of the work which is usually done in platinum. But besides these a large stock of crucibles and ware of silver, nichrome, iron, quartz, alundum, nickel, lead, clay, porcelain and other materials should be on hand, and instructions posted advising for what work crucibles of these various materials are suited. It will be found in many cases that one or another of these materials is very well adapted to the work in which platinum has previously been used.

Many routine analysts work under the impression that platinum is inert to almost any chemical with which he may happen to be working, and some "Dont's" and "Instructions" for its proper use, if posted in the laboratory, would no doubt prevent the ruin of much platinum. In such posters the analyst should be instructed what materials ruin platinum at high temperatures. He should be informed never to place platinum ware in the bare flame or heat it to a temperature approaching a red heat while it contains compounds of lead, antimony, arsenic, silver, tin or bismuth. Also that alkaline earths and caustic alkalies corrode it when heated as well as nitrates and cyanides and sulphur in alkaline mixture. Carbonaceous materials should never be burned in contact with platinum, since small quatities of silica carried by the ash of these materials are reduced by the carbon and combine with platinum, causing it to become brittle.

In heating platinum in the bare bunsen flame it should never be lowered into the reducing cone, but should always be heated in the top invisible parts of the flame. This is also the hottest zone of the flame. The inner cone of a gas flame contains carbon particles and partly burned carbon, which soon crystallizes the platinum and causes it to become brittle due to the formation of a carbide of platinum. If precipitates with their filter paper are ignited in platinum, damage is sometimes caused to the crucible due to the reducing action of the paper. Phosphates and other materials which may injure platinum when reduced in this way should be ignited in porcelain.

Finally, economy and preservation of platinum ware require its proper cleaning. Among the cleaning agents most used are moist sea-sand, with which the platinum is scoured. In some cases fusion with potassium bisulphate may be necessary to clean the metal surface, or sodium amalgam may occasionally be used according to the well known practice.

All the above is of course well known to the average chemist, and the various suggestions made are common practice in all well regulated laboratories. However, in view of the recent difficulty in obtaining new platinum ware and the large investment which the platinum equipment of most laboratories represents, it seemed pertinent again to call attention to some of these rules for the preservation and care of platinum. If calling attention to this matter may help in a little way to extend the life of platinum ware in some laboratories where its conservation and proper use have been neglected, the above will serve its purpose and may assist in conserving the nation's supply of platinum for many essential operations in our industries, in some of which it still finds sole application. Besides this, careful attention to platinum practice may assist in reducing the operating cost in the laboratory where much routine work is handled by analysts with meager technical training.

Dyes and Other Coal-Tar Chemicals

Amendments Recommended to Congress by U. S. Tariff Commission to the Tariff Act of Sept. 8, 1916, Title V on Coal-Tar Crude, Intermediate and Finished Chemicals—New Act to Be Specific—Reasons for Changes

THE United States Tariff Commission has recommended to Congress that the amendments to Title V on Dyestuffs of the act of September 8, 1916, be enacted according to the following edited text, the deleted matter of original act being in brackets and the proposed substitutions or additions in italics. The former act was not sufficiently specific since there were recognized ways of evading duty charges through alternative classifications on such commodities as salol, saccharin, sodium benzoate, phenolphthalein, acetanilid, acetphenetidin, antipyrine, acetylsalicylic acid, aspirin, coumarin, oil of wintergreen, trinitrotoluol, etc. The numbers within the brackets refer to explanatory notes abstracted from the report of Dr. Grinnell Jones on the Reasons for the Proposed Amendments. The full report forms a booklet of 83 pages which is now ready for distribution and to which the reader should refer for further details than given here.

Text Showing Proposed Amendments

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Title V of an act entitled "An act to increase the revenue, and for other purposes," approved September 8, 1916, be and hereby is amended to read as follows:

Title V.—Dyestuffs

Sec. 500. That on and after the day following the passage of this act, except as otherwise specially provided for in this title, there shall be levied, collected, and paid upon the articles named in this section when imported from any foreign country into the United States or into any of its possessions, except the Philippine Islands and the islands of Guam and Tutuila, the rates of duties which are prescribed in this title, namely:

Free List

Group I. Acenaphthene, anthracene having a purity of less than (3) [twenty-five] *thirty* per centum, benzol, carbazol having a purity of less than (4) [twenty-five] *sixty-five* per centum, (5) [cresol] cumol, (7) *cymene*, fluorene, (6) [metacresol having a purity of less than ninety per centum] methylanthracene, methylnaphthalene, naphthalene having a solidifying point less than seventy-nine degrees centigrade, (6) [orthoscresol having a purity of less than ninety per centum, paracresol having a purity of less than ninety per centum] pyridin, quinolin, toluol, xylol, dead or creosote oil, anthracene oil, pitch of coal tar, (1) *pitch of blast-furnace tar, pitch of oil-gas tar, pitch of water-gas tar*, crude coal tar, (1) *crude blast-furnace tar, crude oil-gas tar, crude water-gas tar*, all other distillates (5) *of any of these tars* which on being subjected to distillation yield in the portion distilling below (5) [two hundred] *one hundred and ninety* degrees centigrade a quantity of tar acids less than five per centum of the original distillate, (2) *all mixtures of any of these distillates and any of the foregoing pitches*, and all other products that are found naturally in coal tar, whether produced or obtained from coal tar or other source, and not otherwise specially provided for in this title, shall be exempt from duty.

Dutiable List

Group II. (10) *Acetanilid not suitable for medicinal use*, (11) *alphanaphthol*, (13) *amidobenzoic acid*, amidonaphthol, (13) *amidophenetol*, amidophenol, amidosalicylic acid, (13) *aminoanthraquinone*, anilin oil, anilin (12) [salts] *salt*, anthraquinone, (13) *arsanilic acid*, benzaldehyde (8) *not suitable for medicinal use*, (13) *benzalchloride, benzanthrone*, benzidin, (13) *benzidin sulphate*, benzoic acid (8) *not suitable for medicinal use* (13) *benzoquinone*, benzoylchloride, benzylchloride, (11) *betanaphthol not suitable for medicinal use*, (13) *brombenzol, chlorbenzol*, chlorophthalic acid, (13) *cinnamic acid*, cumidin, (13) *dehydrothiotoluidin, diaminostilbene*, dianisidin, (13) *dichlorphthalic acid, dimethylanilin*, (13) *dimethylamidophenol, dimethylphenylenediamin*, (12) [binitrobenzol] *dinitrobenzod*, [binitrochlorobenzol] *dinitrochlorbenzol*, binitronaphthalene,, *dinitronaphthalene* (13) *dinitrophenol*, (12) [binitrotoluol] *dinitrotoluol*, dioxynaphthalene, (12) [diphenylaimin] *diphenylamin*, (13) *ethylbenzylanilin, hydroxyphenylarsinic acid*, metanilic acid, methylanthraquinone, (11) [naphthol] naphthylamin, naphthylendiamin, nitranilin, (13) *nitroanthraquinone, nitrobenzaldehyde*, nitrobenzol, nitronaphthalene, (13) *nitrophenol*, nitrophenylenediamin, (13) *nitrosodimethylanilin*, nitrotoluol, nitrotoluylenediamin, phenol, phenylenediamin, (13) *phenylhydrazine*, phenylnaphthylamin, (13) *phenylglycocoll, phenylglycocollorthocarboxylic acid*, phthalic acid, phthalic anhydride, (13) *phthalimid*, resorcin (8) *not suitable for medicinal use*, salicylic acid (9) *and its salts* (8) *not suitable for medicinal use*, sulphanilic acid, (14) *thiocarbanilid*, (13) *thiosalicylic acid, tetrachlorphthalic acid, tetramethyldiaminobenzophenone, tetramethyldiaminodiphenylmethane, toluol sulphochloride, toluol sulphamid, tribromphenol*, toluidin, tolidin, toluylenediamin, xylidin, or any sulphoacid or sulphoacid salt of any of the foregoing, (15) *or of any of the products provided for in Group I;* (16) [all similar products obtained derived, or manufactured in whole or in part from the products provided for in Group I] *all other products by whatever name known which are employed in the manufacture of any of the products provided for in Group II or III and which are obtained, derived, or manufactured in whole or in part from any of the foregoing or from any of the products provided for in Group I;* anthracene having a purity of (3) [twenty-five] *thirty* per centum or more, carbazol having a purity of (4) [twenty-five] *sixty-five* per centum or more, metacresol having a purity of

ninety per centum or more, naphthalene having a solidifying point of seventy-nine degrees centigrade or above, orthocresol having a purity of ninety per centum or more, paracresol having a purity of ninety per centum or more; all distillates (17) *of coal tar, blast-furnace tar, oil-gas tar, and water-gas tar* which on being subjected to distillation yield in the portion distilling below (17) [two hundred] *one hundred and ninety* degrees centigrade a quantity of tar acids equal to or more than five per centum of the original distillate; (18) *all mixtures, including solutions, consisting in whole or in part of any of the foregoing except sheep dip and medicinal soaps, not otherwise specially provided for in this act;* all the foregoing not colors, dyes, or stains, (19) *color acids, color bases, color lakes, leuco-acids, leuco-bases, indoxyl, indoxyl compounds, ink powders,* photographic chemicals, medicinals, flavors, (19) *resinlike products, synthetic tanning materials,* or explosives, and not otherwise specially provided for in this title, (20) [and provided for in the paragraphs of the act of October third, nineteen hundred and thirteen, which are hereinafter specifically repealed by section five hundred and two] fifteen per centum ad valorem.

Group III. All colors, dyes, or stains, whether soluble or not in water, color acids, color bases, color lakes, (21) *leuco-acids and leuco-bases whether colorless or not, indoxyl and indoxyl compounds;* (22) *ink powders;* photographic chemicals; (23) [medicinals] *acetanilid suitable for medicinal use, acetphenetidin, acetylsalicylic acid, antipyrine, benzaldehyde, suitable for medicinal use, benzoic acid suitable for medicinal use, betanaphthol suitable for medicinal use, phenolphtholein, resorcin suitable for medicinal use, salicylic acid and its salts suitable for medicinal use, salol, and other medicinals;* (24) *sodium benzoate;* (25) *saccharin,* (26) *methyl silicylate,* (27) *coumarin, and other* flavors; synthetic phenolic resin (28) *and all resinlike products prepared from phenol, cresol, phihalic anhydride, coumaron, indene or from any other article or material provided for in Group I or II, all of these products, whether in a solid, semisolid, or liquid condition;* (29) *synthetic tanning materials;* (30) [or explosives] (31) [not otherwise specially provided for in this title] (30) *picric acid, trinitrotoluol, and other explosives except smokeless powders;* (32) *all of the foregoing* when obtained, derived, [or] manufactured in whole or in part from any of the products provided for in (33) [Groups] *Group* I (33) [and] *or* II; natural alizarin and (34) *natural* indigo, and colors, dyes (34) *stains, color acids, color bases,* [or] color lakes, (34) *leuco-acids, leuco-bases, indoxyl and indoxyl compounds* obtained, derived, or manufactured (34) [therefrom] *in whole or in part from natural alizarin or natural indigo;* (26) *natural and methyl salicylate or oil of wintergreen or oil of sweet birch;* (27) *natural coumarin,* (35) *and all mixtures, including solutions, consisting in whole or in part of any of the articles or materials provided for in this group,* thirty per centum ad valorem.

Sec. 501. That on and after the day following the passage of this act, in addition to the duties provided in section five hundred, there shall be levied, collected, and paid upon all articles contained in Group II a special duty of 2½ cents per pound, and upon all articles contained in Group III (36) [(except natural and synthetic alizarin and dyes obtained from alizarin, anthracene, and carbazol; natural and synthetic indigo and all indigoids whether or not obtained from indigo; and medicinals and flavors)] a speccial duty of 5 cents per pound: (37) *Provided, That the special duties herein provided for on colors, dyes, or stains, whether soluble or not in water, color acids, color bases, color lakes, leuco-acids, leuco-bases, indoxyl and indoxyl compounds, shall be based on standards of strength which shall be established by the Secretary of the Treasury, and that upon all importations of such articles which exceed such standards of strength the special duty of 5 cents per pound shall be computed on the weight which the article would have if it were diluted to the standard strength, but in no case shall any such articles of whatever strength pay a special duty of less than 5 cents per pound: Provided further, That, beginning six months after the date of passage of this act, no package containing any such color, dye, stain, color acid, color base, color lake, leuco-acid, leuco-base, indoxyl, or indoxyl compound shall be admitted to entry into the United States unless such package and the invoice shall bear a plain, conspicuous, and truly descriptive statement of the identity and percentage exclusive of diluents, of such color, dye, stain, color acid, color base, color lake, leuco-acid leuco-base, indoxyl or indoxyl compound contained therein: And provided further, That, beginning six months after the date of passage of this act, no package containing any such article shall be admited to entry into the United States if it, or the invoice, bears any statement, design, or device regarding such article or the ingredients or substances contained therein which is false, fraudulent, or misleading in any particular. In the enforcement of this section the Sccretary of the Treasury shall adopt standards of strength which shall conform as nearly as practicable to the commercial strengths in use in the United States prior to July first, nineteen hundred and fourteen.*

(38) [During the period of five years beginning five years after the passage of this act] *Beginning September ninth, nineteen hundred and twenty-one,* such special duties shall be annually reduced by twenty per centum of the rate imposed by this section (38) [so that at the end of such period] *until September eighth, nineteen hundred and twenty-five, after which date* such special duties shall no longer be assessed, levied, or collected, (39) [but if, at the expiration of five years from the date of the passage of this act, the President finds that there is not being manufactured or produced within the United States as much as sixty per centum in value of the domestic consumption of the articles mentioned in Groups II and III of section five hundred, he shall by proclamation so declare, whereupon the special duties imposed by this section on such articles shall no longer be assessed, levied, or collected.]

(40) *The Secretary of the Treasury is hereby authorized to make regulations for the enforcement of the provisions of this title.*

Sec. 502. That paragraphs twenty, twenty-one, twenty-two, twenty-three, (41) *one hundred and seventy-nine,* three hundred and ninety-four, four hundred and fifty-two, and five hundred and fourteen, and the (41) [words "salicylic acid" in paragraph one of Schedule A of section one] *provision for salicylic acid in paragraph one; and provisions for salol, phenolphthalein, acetanilid, acetphenetidin, antipyrine, acetylsalicylic acid, and as-*

pirin in paragraph eighteen; and the provision for benzoate of soda in paragraph sixty-seven; and the (41) [words "carbolic" and "phthalic"] *provisions for carbolic and phthalic acids* in paragraph three hundred and eighty-seven (41) [of the "free list" of section one of said act] (43) [and so much of said act or any existing law or parts of law as may be inconsistent with this title are hereby repealed] of an act entitled "An act to reduce tariff duties and to provide revenue for the Government, and for other purposes," approved October third, nineteen hundred and thirteen, are hereby repealed: (42) *Provided, That all articles which may come within the terms of paragraphs one, five, thirty-seven, forty-six, sixty-three, five hundred and one, and five hundred and thirty-eight of said act of October third, nineteen hundred and thirteen, as well as within the terms of Group I, II, or III of section five hundred of this act shall be assessed for duty or exempted from duty, as the case may be, under this act.*

Sec. 503. (44) *That on and after the day when this act shall go into effect all of the foregoing goods, wares, and merchandise previously imported, for which no entry has been made, and all of the foregoing goods, wares, and merchandise previously entered without payment of duty and under bond for warehousing, transportation, or any other purpose, for which no permit of delivery to the importer or his agent has been issued, shall be subject to the duties imposed by this act and to no other duty, upon the entry or the withdrawal thereof: Provided, That when duties are based upon the weight of merchandise deposited in any public or private bonded warehouse, said duties shall be levied and collected upon the weight of such merchandise at the time of its entry.*

Sec. 504. (45) *Except as otherwise herein specially provided, this act shall take effect on the day following its passage.*

Reasons for the Proposed Amendments

1. These tars, although similar to coal tar in chemical nature, and yielding similar products or distillation, are not identical. . . . This close similarity makes it advisable to put all the tars on the same basis.

2. In order to insure tarred oils, etc., being retained on the free list instead of being classified under paragraph 5 of the Act of 1913, the amendment quoted above is proposed.

3. Anthracene is obtained by distilling tar to hard pitch at temperatures around 300 deg. C. When the distillate is cooled, crude anthracene, containing from 25 to 30 per cent anthracene, 15 to 20 per cent carbazol, 20 per cent phenanthrene, crystallizes and can be mechanically separated. The next step is to extract the phenanthrene with an oil solvent, which gives a product containing from 35 to 50 per cent anthracene, which can be further concentrated to 80 per cent anthracene by extracting the carbazol with another solvent. This 80 per cent grade is suitable for the manufacture of intermediates directly.

4. The change was introduced to make only the refined carbazol dutiable.

5. It is evident that considerable orthocresol will distill at a temperature of 200 deg. C. (B. Pt. of phenol 191 deg. C.; orthocresol, 191 deg. C.; metacresol and paracresol, each, 202 deg. C.) The alteration is designed to protect the phenol industry and not put a duty on the primary cresol oils.

10. Acetanilid appears in commerce in two grades—medical and technical (an intermediate).

11. Betanaphthol of a medicinal grade should be dutiable in Group III.

12. The hydrochloride of anilin is usually commercially designated by this term.

14. Thiocarbanilid, made from anilin and carbon bisulphide, promises to be of importance as a rubber vulcanization accelerator and is arbitrarily classed in Group II.

21. The use of the term "leuco" has been broadened to include compounds chemically analogous to the original "leuco compounds" even if not colorless — products converted to dyes by an oxidation agent.

22. A dye which might be classed as an ink powder and be consumed in textile dyeing.

28. The products resemble the resins in some physical properties but are different chemically. The term "phenolic" is unduly restrictive—cresol, phthalis anhydride, coumaron and indene should be included.

36. The only dyes of these classes which were made in the United States during 1917 were indigo, dibromindigo and alizarin. The production of indigo during 1917 was 274,771 lb.—made entirely by one company. At the close of 1918, three companies were manufacturing indigo at a rate equal to normal consumption. It is reported that 1,921,327 lb. of "indigo extract" were made from imported natural indigo. Alizarin was refined on a large experimental scale by one producer. Some so-called "alizarin" or "anthracene" dyes were marketed: "alizarin yellow," an azo dye derived from anilin; "alizarin brown" or "anthracene brown," from phthalic anhydride and gallic acid.

37. It is suggested that a specific duty shall be levied on the basis of the usual commercial strength. It is required that the identity and percentage shall be disclosed to facilitate the assessment of both the ad valorem and specific duties.

An Example of Crystal Crushing

In making physical tests of shell steel, it has come to the writer's attention that certain test bars show a very peculiar structure after fracture. The fractured surface shows a crystalline structure with the exception of a spot in the approximate center of the bar which shows a granular and often a silky appearance. This spot varies from approximately one-quarter to one-half the area of the cross section of the test bar. The writer's first opinion was that during the heat treatment of the bar in question the soaking time before the quench was insufficient. In other words, the time was not sufficient to allow the interior of the test bar to reach the critical temperature.

Subsequent investigations disproved this theory, for upon further examination, by taking another section of the same bar and etching, the grain size showed uniform throughout the entire cross section. By notching and fracturing (by impact), another part of the same test bar showed a uniform crystalline structure throughout. These investigations evidently disprove the theory that the heat treatment was not uniform, but indicate rather strongly that the crystals in the interior of the bar were crushed during the elongating of the bar before rupture.

In the writer's opinion, under certain favorable circumstances, this crushing may extend throughout the entire cross section of the test bar. This may lead to erroneous conclusions as to the condition of the steel. The fracture of a test specimen may be reported as silky or granular when in reality it should have been crystalline.

The metal used in the foregoing investigations was a medium carbon steel. The carbon ranged from 0.45 to 0.55 and the manganese from 0.60 to 0.80. The heat treatment was standard for this class of steel. The test bar was cut from a heat treated 4.7-inch common steel shell, taken from the regular production of the Milton Manufacturing Co.'s plant at Milton, Pa.

Electric Furnaces in the Steel Industry and Their Relation to the Central Station Business

Present Status of Electric Steel Furnace Installations and Their Characteristics in the United States—Electric Power Costs and Rate Schedules—Benefit of Off-Peak Load Hour Operating

GENERAL uses of electricity in the steel industry in the past few years have brought this industry to the attention of electrical engineers as perhaps the largest immediate field for new applications of electricity and large requirements for electric power. Foundries, rolling mills and all forms of steel fabricating plants are so rapidly adopting equipment which requires large amounts of electric power that the question of providing the necessary power is one which demands special attention. These uses of power are varied and some of them are more or less complex, so the services of competent electrical men, either in attendance or available for emergency call, are necessary. These uses comprise general motor drive, rolling mill motor drive requiring special control equipment, welding service for arc, spot and butt welding, oven service for heat treating furnaces, core baking ovens, enameling ovens, etc., lighting service and, lastly, by far the largest of all, service for electric steel furnaces. Electric furnaces require relatively large amounts of power, and their adoption in medium size plants often increases the demands for power as much as 1000 per cent. Since the electric melting furnace is of most vital importance at this time, the following comments will refer particularly to this type of equipment.

Electric Steel Furnaces

There are, according to reports, now in the neighborhood of 300 electric steel furnaces in operation in America. Some of them are located in large steel plants, but the greater number are located in small and medium size steel foundries. Extension in the use of these furnaces is dependent upon an adequate supply of reliable electric power, available at a rate that will enable electric furnace steel to compete with steel produced in other types of furnaces. It is important that the cost of power be as low as the economies of modern large generating and distributing systems will permit, but it is equally important that the supply be adequate and that the service be reliable. Electric furnace installations are invariably followed by complete electrification of the steel plants, and in view of the fact that steel plant operators in general cannot expect to be thoroughly familiar with the various types of electrical equipment involved, it is important that competent electric service men be available for immediate call in case of trouble or in case changes are necessary or additional equipment is required.

Relatively few electric furnaces have been installed in this country excepting where power has been available from the lines of power companies. For this reason furnace manufacturers throughout the early stages of the development have worked hand in hand with power companies, and it should be recognized that the status of the electric furnace to-day is in no small degree due to the careful and persistent efforts of power company industrial and operating engineers.

Furnace Electrical Characteristics

Electric arc steel furnaces have operating characteristics quite different from those of any other electric-power-using equipment. In the early stages of their development chief consideration was given to thermal efficiency, and with this idea in mind a number of furnaces were constructed which proved to have very objectionable electrical characteristics. Among these were induction furnaces with a power factor so low that power could not be supplied to them either satisfactorily or economically. The single phase, long arc furnace followed, which gave not only an intolerably low power factor but required single phase power, placing an unbalance on the generally used three phase power distributing system which introduced difficulties in power distribution that were very objectionable. It was soon found that three phase, short arc furnaces equipped with suitable regulators could be made and would not only accomplish all of the metallurgical requirements but would draw a practically balanced load from a three phase line and produce a minimum of load surging and voltage fluctuation on the line. Furnaces of this type immediately appealed to the electrical men as a step in the desired direction and demonstrated that there is no further necessity to supply power to a low power factor or single phase furnace, unless perhaps to some of very small capacity. We may therefore now consider single phase and low power factor furnaces out of the question and impracticable on account of electrical difficulties.

With even the most improved types of furnaces it is necessary to obtain power from a relatively large generating capacity and to have adequate conductors all of the way from the generators to the furnace. There are wide variations in the power load during a heat, particularly in the melting down stages of a heat of cold scrap. In this period there is a series of instantaneous short circuits causing very heavy loads, interspersed with conditions where the metal changes position and the load is very light. The result is a series of sudden load fluctuations which make it extremely difficult to maintain reasonably constant voltage on the lines and at the generating plant. Unless the power station generating capacity is many times greater than the load drawn by the furnace and unless the lines to the furnace are amply large, the effects of the load fluctuations at the furnace will reverberate through the transmission and generating system to such an extent that the

power plant will be unable to supply other power loads with any degree of satisfaction. For this reason a power company with a small central station should consider the possible effects of a furnace load quite carefully before agreeing to supply it.

Sources of Power

While electric power for a steel furnace may be obtained either from the lines of a power company operating steam or water power plants, or from a special or isolated power plant employing any suitable form of generating equipment, the electrical characteristics of large arc furnaces are such that they can be supplied with power far more satisfactorily and economically from a large generating and distributing system than from a relatively small isolated power plant. Variation in the electric load of a furnace during a heat and sudden heavy loads drawn from the line due to short circuits in the early stages of a heat make it necessary to have generating equipment for an isolated plant at least twice as large as the average load drawn by the furnace. This makes the investment in power plant equipment high, and the low load factor resulting would cause relatively high operating costs. In view of the fact also that furnace installations of from 1½ to 5 tons capacity require a total investment of between $25,000 and $50,000, it would be hardly practicable for the steel company to make an additional investment in power plant equipment in the neighborhood of $100,000.

The usual practice is to obtain power from a central station generating plant and distributing system of as large capacity as is available. It matters not, except in the question of rates in some cases, whether the power is generated by steam or water power. In addition to having large generating capacity and heavy feeders necessary to supply furnace power, central stations usually have an adequate construction and trouble force available for taking care of troubles, repairs and additions in connection with the electric equipment. This, I believe, has been found to be an extremely valuable asset to the steel company in practically every case.

Power Companies Learning by Experience

Power companies have had to learn the characteristics of electric arc furnaces by experience. A number of them have held back on supplying power until they saw the effects of a furnace load and obtained some definite information regarding a rate for furnace power equitable from the power companies' standpoint. Some of them, however, of a more pioneering nature, took chances on some of the early installations and have spent large amounts of time and money in helping to develop furnaces to the point they have reached today. Successful future operation of electric steel furnaces will doubtless depend to a large extent upon close coöperation among furnace builders, steel plant operators and power companies, and it therefore behooves those in these different branches of industry to work together. If the proper types of furnace and accessory equipment are installed so the electric loads will not be too difficult to take care of on a standard power system and if the business will bear a remunerative rate, power companies will be more than glad to supply all of the electric power required and also will contribute quite materially in the line of coöperation in the installation and maintenance of the furnace equipment.

Electric Power Costs

In the operating costs of an electric steel furnace, power is one of the appreciable items. In melting down cold scrap as in foundry work, it often amounts to about 20 per cent of the melting cost. This varies, of course, with the cost of labor and scrap and it also varies with the type of furnace used and the conditions of operation. Under normal nonwar conditions 1c. per kw.-hr. is a very reasonable rate for furnace power, but under present war conditions 1½c. per kw.-hr. is not unreasonable. There is probably little variation in the amount of power used and consequently in the power cost for the different types of the latest improved furnace, the greatest variation being due to the size of furnace used for a given output and the manner in which it is operated. A given capacity of electric power involves a fixed investment and carrying charge, whether it is obtained from an isolated power plant or from a power company, and with the necessary capacity provided and these charges once established they must obviously be distributed over the number of tons of steel melted by the furnace.

Electric Power Rate Schedules

In most cases electric power in the quantities required by steel furnaces is sold under a rate schedule having two factors: (1) a demand charge, or price per kilowatt for the maximum use of power during any given period in a month, such as ten, fifteen or thirty consecutive minutes; and (2) an energy charge, or price per kilowatt-hour for energy used in a month as measured by an integrating wattmeter. The demand charge covers the fixed carrying charges on power station, generating equipment and distribution system investment, and the energy charge covers the variable costs involved in the generation and distribution of electric power, such as fuel, labor, supplies and line losses.

On a two charge rate schedule it is apparent that the resultant rate per kw.-hr. earned is dependent to a large extent upon the number of hours the maximum demand is used in a month, because the demand charge is established by the use of power for a given short period, of say fifteen consecutive minutes, and is the same for the month in question whether power is used for fifteen minutes or 730 hours. The energy charge depends upon the total number of kilowatt-hours used, but there are often decreasing steps in the energy charge schedule so that the greater the quantity of power used the more will be obtained on the lower steps of the rate and accordingly the total net resultant rate will be decreased. This form of rate schedule is perfectly fair to the power user and it is practically the only equitable form of rate schedule under which a power company can furnish power, particularly steam generated power.

Obviously, the advantageous method in operating an electric furnace is to operate it as many hours a day as possible. If a 6-ton furnace operating ten hours a day will take care of a foundry's requirements, they can be taken care of also by a 3-ton furnace operating twenty hours a day. Night forces of men doubtless do not work quite as efficiently as day forces and in a close

labor market they are harder to maintain, but only a few men are required in melting and pouring gangs and in view of the apparently lower power cost that can be achieved there is a decided advantage in operating at night. This may be shown by the following example:

Advantages of Operating at Night

Suppose we have to melt 234 tons of steel per month and consider using either a 3-ton furnace making three heats a day or a 1½-ton furnace making six heats a day; assume that the 3-ton furnace requires a maximum fifteen-minute demand of 900 kw. and the 1½-ton furnace a demand of 450 kw., that 550 kw.-hr. per ton melted are required in either case and that electric power is purchased under the following rate schedule:

Demand Charge—200 kw. at $1.67 per kw. per month; all over 200 kw. at $1.25 per kw. per month.

Energy Charge—50,000 kw.-hr. at 0.7c. per kw.-hr.; all over 50,000 kw.-hr. at 0.5c. per kw.-hr.

In both cases 234 tons of steel are melted, and at 550 kw.-hr. per ton, 128,700 kw.-hr. of electric power are used. In the first case the maximum demand is 900 kw., the demand charge $1208.33, the energy charge $743.50 and the total cost $1951.83, which amounts to 1.52c. per kw.-hr. and $8.35 per ton of steel melted. In the second case the maximum demand is 450 kw.-hr., the demand charge $645.83, the energy charge $743.50 and the total cost $1388.83, which amounts to 1.08c. per kw.-hr. and $5.93 per ton of steel melted. From this we see that by using the small furnace we save $2.42 per ton of steel melted.

Power Factor Is Important

Electric power generating equipment and distributing lines are affected quite materially by the power factor of the power using equipment. Power factor is the ratio of the real power to the volt-amperes in an alternating current circuit. It is expressed in a per cent and is the number by which the volt-amperes must be multiplied to obtain the real power. Real power (P) in a three phase, alternating current circuit is expressed by the product of volts (E) $\times$ amperes (I) $\times$ the constant 1.73 $\times$ power factor (PF), while volt-amperes are expressed simply by volts $\times$ amperes $\times$ 1.73, or P equals 1.73EI and PF equals 1.73PEI. It is apparent, therefore, that for a given amount of real power supplied the current in the generating equipment and distributing lines varies inversely as the power factor. Real power is what is sold, but current is what determines the size of the generating and distributing equipment. If a given power load with unity, or 100 per cent, power factor requires generating and distributing equipment of a certain capacity, the same power load with 50 per cent power factor will require generating and distributing equipment of twice the capacity. The investment will increase accordingly, and naturally the fixed carrying charges will increase directly with the investment. In addition to the increased investment there are a number of operating and metering difficulties due to low power factor.

For these reasons power companies find it necessary to require the highest practicable power factor, and power contracts should therefore contain power factor clauses covering the manner in which power factor will be treated in computing the cost of power under the stipulated rate. The latest types of electric steel furnaces can easily be operated at a power factor between 80 and 95 per cent, and it is very objectionable if a power factor of 75 per cent or lower is obtained.

In the generation of electric power in a steam plant, fuel constitutes one of the chief items of cost, amounting to something over 50 per cent. For a number of years the cost of fuel, particularly coal, has been fairly stationary and power rates have been based on the average cost from year to year, no special provision being made for appreciable increases or decreases. The marked increase in the past two years, however, of something over 100 per cent, brought about by war conditions, has shown the necessity of having a provision in power contracts that will vary the energy charge according to the cost and quality of coal used. Some power companies base their schedule rate on a given cost of 1,000,000 B.t.u. in coal delivered in the company's coal bunkers, and then add to or subtract from the energy charge a stipulated amount for each increase or decrease of 1c. in the cost of 1,000,000 B.t.u. This factor, sometimes called the "coal cost factor," takes care only of variations in coal cost; labor, the other principal item of cost involved, can be treated in a similar manner by using a stipulated base price per "man hour" for labor and varying the energy charge according to increases or decreases above or below that base price.

Long-Term Power Contracts Impracticable

One thing is apparent, and that is that power companies cannot afford to make long-term power contracts at a fixed rate. Rate regulating bodies in the different states, of course, have authority to revise rates at any time and even though they are stated specifically in contracts, they may be changed. Revisions by these bodies, however, require appreciable expenditures of time and money in assembling data and preparing cases and often decisions are reached only after a prolonged delay. It is far better, therefore, that contracts cover probable necessary rate variations as fully as possible.

Load factor is a term referred to by power generating and distributing companies perhaps as often as any other term. It has a direct bearing on the cost of purchased electric power under a rate having a demand and an energy charge as discussed in a foregoing paragraph. It is the ratio of the average power load of a plant to the maximum load for a certain period of time. It is more specifically thought of as the ratio of the number of kilowatt-hours used by a plant in a month to the product of the maximum demand of the plant and the total number of hours in the month, which averages 730. Thus a plant having a maximum demand of 1000 kw. and using 365,000 kw.hr. in a month has a "load factor" of 365,000 $\div$ 1000 $\times$ 730, which equals .50, or 50 per cent.

The reason this term is so important to power companies is that the load factor of the generating plant has a very decided effect on the cost of generating and distributing electric power. Power generating and distributing equipment has to be of ample capacity to take care of the maximum load it is called upon to carry, so the investment is fixed by the maximum load, and consequently the annual fixed carrying charges covering interest, depreciation. taxes and insurance

are fixed. Further than this, power plants must be operated twenty-four hours every day and practical normal operating forces must be maintained regardless of the magnitude of the loads on plants and distributing systems. Labor costs, therefore, change but little whether loads exist for twenty-four hours or for but a few hours a day.

Benefit of Operating During "Off-Peak" Hours

Factories, office buildings and commercial and industrial establishments in general are normally in operation from eight to ten hours a day, starting from 7 to 8:30 o'clock in the morning and closing between 4:30 and 6 in the afternoon with from one-half to one hour shut-down at noon. In winter months the lighting load in offices and factories particularly is heaviest between 4:30 and 7 o'clock in the evening. If the generating plant also supplied power for operating street cars, which is usually the case in larger towns and cities, this load will be found heaviest at the time of the afternoon and evening lighting peak. It is a general condition, therefore, that the central station generating plants and distributing systems have to be equipped to take care of a relatively heavy peak load in the late afternoon, particularly of the winter months, and that for these peaks they have to maintain equipment which is idle at other times. It is at once apparent that a power load which is not used during the peak hours will not require additional generating capacity and corresponding investment and will not increase operating labor costs and consequently can be supplied at a lower rate than "on-peak" power. This kind of a load has attracted the attention of central station companies and most of them are glad to furnish off-peak power at a properly reduced demand charge and correspondingly reduced overall rate. Since electric steel furnaces can very easily be shut down during these peak load hours, furnace operating companies may benefit materially by considering this point when negotiating power contracts.

Similar consideration should also be given to night loads. In some cases furnaces may take care of the desired output by operating only at night, say between 7 p.m. and 7 a.m., and where this can be done a substantially low power rate may be obtained.

Disposition of Munitions

Mr. Benedict Crowell, Assistant Secretary of War and Director of Munitions, has been requested by the President to assume responsibility for the proper disposition of all property acquired by the War Department since April 6, 1917. Mr. Crowell has appointed Mr. C. W. Hare, Assistant Director of Munitions, to have general supervision of this work, and Brig. Gen. C. C. Jamieson has been appointed Director of Sales in direct charge of an organization to be perfected for the disposal of surplus property. It is the intention of the Director of Munitions so to market Government property as to interfere as little as possible with business conditions, and to this end the Assistant Director of Munitions and the Director of Sales will, as occasion may require, confer with committees representing the industries affected.

Information will be furnished by either the Assistant Director of Munitions or the Director of Sales at their offices in the Munitions Building, Nineteenth and B Streets, Washington, D. C.

Separation of Potash Salts

By H. P. Bassett, Ph. D.

In Chemical & Metallurgical Engineering for the past few months much has been written on the potash outlook for this country. Many sources have been discussed, but the potash industry of this country, like the explosive and the allied chemical industries, will be compelled to undergo a decided change.

Potash derived from many of our present sources, such as wood ashes, Western lake brines, etc., will not be suitable for the market under the present system of production. Potash from such sources carries large amounts of other alkali salts, such as sodium carbonate, chloride, sulphate, borax and small amounts of the alkaline earth salts.

These crude salts are used today in our great emergency, but they are not suitable for many trades, especially the fertilizer trade, on account of their high content of other salts, particularly sodium carbonate, which, as is well known, reverts the phosphoric acid when added to acid phosphate fertilizer.

It is also claimed that borax in too large quantities has an over-stimulating effect on plant life. Some authorities, however, state small amounts are beneficial. These points, however, need much further investigation and during the meantime the trade will adhere to the old standards as closely as possible.

National Duty for Chemists

It appears to the writer it is a national duty for the chemical profession to put our present sources in shape to meet the demand they will eventually meet in a peace-time basis. It would certainly be a calamity to let the present sources, such as the Western brines, go out of business on account of the necessary data on which to put them in a healthy condition.

The writer is speaking in general terms, but to illustrate the point more clearly a definite case will be pointed out. For instance, the Nebraska brines usually run about one-third potassium sulphate, one-third sodium sulphate and one-third sodium carbonate. This, however, is sometimes varied by a substantial percentage of sodium chloride. With this illustration before us, it is easily seen with the Nebraska location and the composition of these salts, if those constituents were separated each would have a market value and this field is within the freight radius of some of our best markets for salt cake and sodium carbonate. Of course, the potash would stand shipment even to the last want.

It is, however, different with the case of the brines further West, as these by-products have a very limited market on the West coast. But even in this case shipping high-grade potash salts they could demand the highest price and also save the probable cost of separation in the difference in freight rates.

The writer for several years was interested in the production of potash salts, especially from the silicate, such as feldspar, glauconite, etc., and during the investigation of this work was placed in a similar position as outlined above. That is, in order to make both ends meet, the products produced had necessarily to be separated economically.

With this in view the problem of separation was studied extensively and a number of important points were brought out which may be stated as follows:

1. It is almost impossible to separate a three ion system, for example potassium sulphate and sodium sulphate. This is either due to the formation of double salts or the salting out of one salt by the other on account of common ion. This may be overcome in this instance by the addition of common salt, which has two effects—it produces a four ion system and also tends to salt out the salt with a common ion, namely, sodium sulphate.

2. There is that tendency in any four ion system to form the greatest opposites possible. To illustrate this point, in the above system after the addition of the salt, the greatest opposite that could be formed is potassium chloride and sodium sulphate, consequently the potassium chloride remains in solution while the soium sulphate is precipitated on evaporating the solution.

3. The presence of an alkali or a salt acting as an alkali tends to throw down the heavy acid salts as they exist in solution. To illustrate this point, if we have sodium carbonate or sodium acetate (a weak acid salt which acts as an alkali) the salts, potassium sulphate and sodium sulphate, will tend to be thrown down in the proportion they exist in solution, and this condition will be nearer and nearer approached on evaporating the solution on account of the increase in concentration of the alkali salt. Consequently in the case where we have an alkali present the heavy acid salts like potassium sulphate and sodium sulphate, potassium chloride and sodium chlorite, will have to be thrown out of solution to free them from carbonate and then separated, adhering to the four ion system.

As to how these three so-called laws shall be operated depends on local conditions and original composition of the brines to be dealt with.

Some Laboratory Results

It might not be out of place here to give some of my own laboratory results in a particular case I was dealing with at the time. In the case I had to deal with, the salts in solution were sodium sulphate, potassium sulphate and a small amount of sodium chloride, but, as you will see later, not enough to take care of all the potash.

The analysis of the solution was as follows:

Sp. Gr.	1.100
Total solids in 100 cc., grams	11.340
Total solids by weight, per cent	10.490

Analysis of total solids:

Potassium sulphate, per cent	9.19
Sodium sulphate, per cent	78.35
Calcium sulphate, per cent	0.56
Sodium chloride, per cent	11.90

Of this stock solution 2000 cc., to which was added 20 gr. of salt, was evaporated until a quantity of salts was precipitated. These salts were washed three times on a funnel with hot water, weighed and analyzed with the following results:

FIRST SALT CROP

Weight, grams	54
Sodium chloride, per cent	0.57
Sodium sulphate, per cent	99.29
Potassium sulphate, per cent	0.14

The mother liquor which was wash waters and 1320 cc. more of stock solution to which was added 14 gr. of salt was returned for further evaporation. Four salt crops were then taken out in succession, the weight and analysis as follows:

SECOND SALT CROP

Weight, grams	98.50
Sodium chloride, per cent	0.20
Sodium sulphate, per cent	99.34
Potassium sulphate, per cent	0.46

THIRD SALT CROP

Weight, grams	73.40
Sodium chloride, per cent	0.13
Sodium sulphate, per cent	99.40
Potassium sulphate, per cent	0.47

FOURTH SALT CROP

Weight, grams	35.95
Sodium chloride, per cent	2.08
Sodium sulphate, per cent	89.60
Potassium sulphate, per cent	8.32

After removing the fourth salt crop, 65 gr. of sodium nitrate were added, dissolved in as small a quantity of water as possible, the object being to convert the potash salts into potassium nitrate. This solution was now evaporated and a fifth salt crop taken, which was washed three times with hot water and which gave the following analysis:

FIFTH SALT CROP

Weight, grams	39.20
Potassium sulphate, per cent	0.43
Sodium chloride, per cent	50.06
Sodium sulphate, per cent	48.28
Sodium nitrate, per cent	1.23

The mother liquor was then cooled to room temperature, when potassium nitrate separated out. This was washed three times with cold water and in analysis gave the following results:

Potassium nitrate, per cent	92.96
Sodium chloride, per cent	0.50
Sodium sulphate, per cent	0.39
Sodium nitrate, per cent	6.15

It will be seen that the first three salt crops are good marketable sodium sulphate. The other salt crop and also the mother liquor would be returned to the evaporator and recovered with a new lot of solution to be evaporated, the fifth salt crop furnishing the sodium chloride needed.

The above potassium nitrate can now be recrystallized to produce a pure product or converted into potassium sulphate, as outlined below. The potassium nitrate was converted to potassium sulphate by adding 12 gr. of sodium sulphate from first salt crop to 18 gr. of potassium nitrate. The solution was now evaporated and the potassium sulphate came down from hot solution above grade, analyzing 49.18 per cent K_2O. equivalent to 88.53 per cent K_2SO_4.

The manufacture of sulphate by this process necessitates an extra step, but as none of the nitrate is lost in the operation, the cost will be in the operation.

The sodium nitrate solution can be returned to the point where the nitrate was added; thus the only additional evaporating cost will be in the evaporation of the water added in the dissolving of potassium nitrate and sodium sulphate.

It can be readily seen from the discussion set forth above that by this or some other method it is entirely feasible to produce our potash salts in a high grade form and also recover the other products in marketable form. It might be not out of place and also of interest to note in this connection that by the above procedure the writer has been able to produce ammonia nitrate from ammonia sulphate. In fact the three statements seem to hold for all alkali salts or sodium salts and if followed will, no doubt, form a basis for work much needed at present.

Distillation of Coal at Low Temperature*

THE distillation of coal at a high temperature, such as is actually practiced in gas retorts to extract illuminating gas, takes place under unfavorable conditions from a thermal point of view. According to results obtained by M. Euchène, only 12 per cent of the heat produced by combustion is available for distillation. M. Guénguen, relying on the fact that transmission of heat through the retorts is slight and that this transmission decreases in proportion to the distillation, set about to determine whether it would not be profitable to induce distillation by the introduction of a current of steam superheated to from 500 to 700 deg. His investigations showed several advantages: Shorter distillation periods, distillation accomplished more quickly and more directly, easier liberation of the gas by entrainment and operation at lower temperatures.

In addition, it was of great interest to know whether the coal itself could serve as a raw material for the manufacture of the aromatic compounds as well as for that of the hydro-aromatic and aliphatic compounds, obtained up to the present time from coal tar.

Distillation in a Vacuum

Moreover, attempts have long been made to obtain a better utilization of the coal either by distillation in a vacuum or by distillation at low temperature. Up to now, distillation in a vacuum, studied especially by Berthelot and Pictet, has had no practical application.

In distilling coal under a pressure of 20 mm. of mercury at a maximum temperature of 450 deg., Pictet has obtained 4 per cent of liquid coal tar, containing neither naphthalene nor anthracene, both of which are characteristic of coke-oven tar; however, in heating this tar red hot in incandescent tubes, it is transformed into ordinary tar. Pictet states that the tar obtained in a vacuum contains a greater quantity of phenol than crude petroleum and does not polarize light.

The distillation of coal at low temperature, on the contrary, will perhaps find an immediate and practical realization, thanks to the investigations instituted for this purpose at the special institute for the study of coal created at Mulheim on the Ruhr. (See Génie Civil, March 10, 1917, p. 165.)

Investigating Mineral Oils

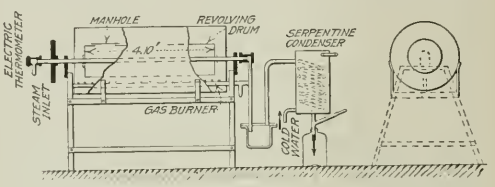
This Research Institute, created by the Kaiser Wilhelm Society to contribute to the development of theoretical and applied sciences, has concerned itself particularly up to the present time with practical questions of immediate interest, notably, the investigation of mineral oils. We know that since the war Germany has lacked oils of all kinds. Lubricating oils which are now used are for the most part mineral oils extracted from petroleum and imported largely from America. It would be very advantageous then for Germany to be able to extract the lubricants which she needs from the coal by distillation.

The investigation of new sources of volatile products, of lubricants or of motor oils has led this institute to undertake a minute study of the chemical nature of coal and also of coal distillation at low temperatures.

*Translated from *Le Génie Civil*, July 7, 1917.

This question is not new; already in 1906 Börnstein, of Berlin, published (Journal für Gasbeleuchtung, Aug. 4, 1906) results of a systematic investigation made by him on the distillation of coal at atmospheric pressure and at a temperature no higher than 450 deg. The coke used was friable and porous, and useless in metallurgy. It yielded a brown tar in a proportion of 3 per cent for the rich coals and 10 per cent for the flaming coals and those not containing free carbon. These tars, studied by Börnstein, were in reality paraffines melting between 55 and 60 deg. and containing up to 28 per cent acid products; the oily elements of the tars, freed of basic and acid compounds, contained neither naphthalene nor anthracene.

Below 350 deg. it contained no solid bodies; above 350 deg. paraffines were obtained; the benzols did not contain thiophene. The quantity of gas obtained was



LOW TEMPERATURE APPARATUS FOR DISTILLING COAL — TRANSVERSE SECTION

small, 17.6 liters of gas per kilogram of flaming coal from the Bismarck mine yielding 10 per cent tar.

In England some companies were formed for the distillation of coal at low temperature, among others the Coalite Company, which obtained in place of coke some coalite or semi-coke (See Génie Civil, March 14, 1918, No. 20, p. 348) which can be used as smokeless fuel, but the tar yield was very large and the coalites too friable.

Apparatus Used by German Institute

In a conference on the actual state of the coal investigations held March 6 at the General Assembly of German Iron Masters and repreduced in Stahl und Eisen, April 12 and 19, Prof. Franz Fischer, director of the institute for the study of coal, discussed at great length the distillation of coal at low temperatures and described the apparatus used for this purpose by the German Institute.

This laboratory apparatus, represented in the illustration, is composed of an iron cylinder containing the combustible, heated by a gas flame and arranged to rotate slowly around on its axis (3.5 turns). With this arrangement, the particles of coal heated by direct contact with the walls cannot be overheated, for the layer in contact with the walls is constantly being replaced. Moreover, since the particles commencing to distil are brought back to the surface, the tar vapors do not encounter the layer of coal again, but are entrained and carried out of the drum by a current of steam introduced through the hollow shaft. An electric precision thermometer serves to show the temperature of the apparatus during the operation. The apparatus is completed by a deposit chamber and a coil immersed in water.

With this apparatus, complete distillation of coal is effected in one or two hours and there is obtained with rich coal 3 per cent tar, and with flaming coal 10 per

cent tar, the composition of which is indicated in Table I.

M. Fischer says that by this method of distillation they obtained tars free from naphthalene and anthracene and containing paraffine. After the separation of the phenols, by distillation with superheated steam one can extract from the tar the lubricating oils forming 10 to 15 per cent of the weight of the coal and resembling those obtained in the treatment of coal by liquid SO_2. These lubricants, red-gold in color and possessing a pleasing odor, are mixtures of oil. They have been able to extract lubricating oils from them which ignite at 200 deg. and have, at 50 deg. temperature, a viscosity of 2 deg. to 28 deg. (Engler). The oils set down in Table I as non-viscous are oils having the character of

TABLE I—COMPOSITION OF TARS EXTRACTED BY DISTILLATION OF COAL AT LOW TEMPERATURE

Composition, Per Cent	Tar from Rich Coal	Tar from Flaming Coal
Highly viscous oils (lubricants)	15.2	10.0
Paraffines	0.4	1.0
Non-viscous oils	33.5	15.0
Phenols	14.0	50.0
Resin	4.2	1.0
Residual tar	19.2	6.0
Losses and water	13.5	17.0
Total	100.0	100.0

petrols and containing unsaturated hydrocarbons and true olefines of the formula C_nH_{2n}. They have been able to establish the fact that they polarize light weakly, which is quite characteristic of petrols.

Gases of High Calorific Value

The gases obtained during the distillation have a very high calorific value, about 9000 calories, and have a volume of 40 liters per kilogram of rich coal and of 50 liters per kilogram of flaming coal. This high calorific value is due to the presence of 70 per cent methane, ethane and heavy hydrocarbons.

They have not been able to separate the light hydrocarbons from the gases of distillation by the ordinary method; to accomplish this, they have had to distil the gases by steam after compression of 20 atmospheres in the presence of paraffine oil. They have thus obtained aromatic carbons in an amount of 0.2 to 0.3 per cent of the weight of coal boiling between 20 deg. and 100 deg. and containing almost no benzol. These hydrocarbons are a mixture of volatiles the specific gravity of which at 20 deg. is about 0.65. They yield different kinds of petroleum derivatives in distilling, such as petroleum ether, ligroin, light and heavy benzines. The tar still contains very nearly as much of these benzines, or a total of 0.3 to 0.6 per cent of the weight of coal.

These bodies, the exact chemical nature of which is not yet known but the analysis of which shows 83.5 per cent carbon and 14.5 per cent hydrogen, are more hydrogenated than benzol (7.5 per cent) and its homologs.

From the experiments made up to this time one can conclude that, if the distillation at low temperature is carefully conducted, it is possible to extract from the coal all the industrial products of petrol: paraffines, lubricants, benzines, oils.

The economic success of this distillation at low temperature depends particularly on the utilization of the coke produced. This should be obtained adequately solid; if not producers should be set up near the distilling apparatus, so that the coke can be used while still warm.

Already, thanks to the labors of Messrs. Parr and Olin at the University of Illinois, it has been possible to improve the quality of the coke obtained by mixing finely pulverized coal with the coke dust and compressing the briquet of coal during the distillation.

Chrome Sands on the Pacific Coast

By Justice F. Grugan*

In view of the extensive reports published by the U. S. Geological Survey,[1] it is not surprising that interest has been revived in the black sand deposits of the Pacific Coast, especially during the recent period when war minerals, notably chromite and platinum, were urgently sought for the Government.

Occurrences of black sand are widespread. Not only are the beaches of California and Oregon rich in natural concentrations of black sands, but many inland water courses as well. A microscopic examination of samples of these sands from many different localities reveals a certain uniformity of species and physical condition of the component mineral particles. Their proportion, however, varies to a marked degree. This variation is explained by the different conditions in the original formations from which these black sands were derived. Chromite is known to have its origin in magmatic segregation during the formative period of the peridotites and serpentines. Its subsequent liberation by erosion and decomposition, its transportation by water and the final localization of the heavier grains are processes whose occurrence is amply verified by the testimony of geological formations and the beach and river sands.

During an examination begun in June, 1918, of beaches and ancient marine deposits lying between Crescent City, California, and Bandon, Oregon (a distance of approximately 125 miles), frequent panning and magnetic tests showed that the proportions of chromite and platinum increased appreciably as the investigation proceeded northward.

Historical Notes

Fifty or sixty years ago the pioneer placer miners discovered a stratum of black sand, rich in gold values, located in the vicinity of Cut Creek, two miles back from the beach and about six miles north of what is now the City of Bandon in Coos County, Oregon. Tales of wild but prosperous communities in the old Randolph mining district are confirmed by a few desolate ruins of log cabins, partly buried by the encroaching drifts of sand. Many evidences are seen of futile attempts to win fortunes from these elusive sands. In one place, half buried, lies a complete drag bucket equipment, rusty and rotten; close by stands a large concentrating mill with strange types of zigzag riffles, screens, trommels and assay furnaces.

One beach relic of striking outline consists of a huge automobile dredge and concentrator. Great drumlike wheels of steel plate support an intricate superstructure, which houses an engine, a boiler, sluice and bump-

*Engineer, Suffern Co., N. Y.

[1] David T. Day and R. H. Richards in Mineral Resources of the U. S., 1905.

ing boxes and finally a ponderous bucket excavator driven by massive pinions, gears and sprockets. A single trial of this $20,000 machine showed that it could nose in successfully, but was unable to withdraw from the cavity so created. It should be mentioned, however, that these failures or so-called "monuments" resulted from many attempts to extract gold and platinum from the beach sands. The idea of treating ancient marine sands or "back beaches" primarily for chrome values is the outcome of war-time necessity and largely dependent upon consequent prices for success.

Origin of Cut Creek Chrome Sands

The Old Lane Mine, on the south branch of Cut Creek, was operated in the early days chiefly by underground methods and by the removal of light sand overburden. In thickness the deposit averaged six feet and underlaid several acres of ground at depths of from ten to thirty feet. The formation is probably of comparatively recent origin, as trunks of trees were sometimes encountered in the workings and displaced only with considerable difficulty and expense. The black sand was mined by pick and shovel and dumped into sluice boxes. Various devices were used to collect the gold and heavier "white metal" platinum, which, it may be stated in passing, was much despised, as it reduced the selling value of the gold, and if sold separately brought only 50c. an ounce. The rejected black sands were washed down Cut Creek and allowed to settle in a low swamp termed the "Lagoon."

The area of the "Lagoon" covered by these tailings is 2200 feet in length and from 30 feet at its narrowest limits to 220 feet at its greatest width. The surface measurement is approximately 5.8 acres, and the deposit is from one to eight feet deep. Where the soil has mixed with the sand to a depth of several inches it is covered by vegetation and a few small trees.

Character of the "Lagoon" Sands

The observer is impressed with two characteristics in studying this particular deposit. First, the average fineness of the individual grains, about 93 per cent of which will pass through a 40-mesh screen. Second, the variety of mineral constituents, chief among which, in the order of their proportionate amounts, are:

Mineral	Proportionate Per Cent.
Chromite	45
Garnet	30
Quartz and other silicates	20
Magnetite and ilmenite	3
Zircon and monazite	2
	100

This composition is not typical of Pacific Coast black sands. The percentage of chromite is unusually high and differs widely from similar appearing sands of the southern beaches which frequently contain over 50 per cent of magnetite. The individual particles are very fine and rounded but the deposit contains no slimes. The material weighs from 109 to 159 lb. per cubic foot, depending upon the variation in metallic constituents.

Tonnage and Analyses

The "Lagoon" has been carefully prospected by a series of pits at 50 foot intervals, sunk along forty-five parallel lines. A total quantity of 25,000 tons has been calculated, which averages 22.536 per cent chromic oxide, Cr_2O_3. Remarkable uniformity is shown in the results here presented:

Line	Per Cent.	Line	Per Cent.
1 Cr_2O_3	24.05	23 Cr_2O_3	24.05
2 Cr_2O_3	24.05	24 Cr_2O_3	24.06
3 Cr_2O_3	22.2	25 Cr_2O_3	24.5
4 Cr_2O_3	23.05	26 Cr_2O_3	21.8
5 Cr_2O_3	21.8	27 Cr_2O_3	23.0
6 Cr_2O_3	22.2	28 Cr_2O_3	18.6
7 Cr_2O_3	20.5	29 Cr_2O_3	21.8
8 Cr_2O_3	21.4	30 Cr_2O_3	19.5
9 Cr_2O_3	26.5	31 Cr_2O_3	14.1
10 Cr_2O_3	23.05	32 Cr_2O_3	20.4
11 Cr_2O_3	24.1	33 Cr_2O_3	21.8
12 Cr_2O_3	23.9	34 Cr_2O_3	21.8
13 Cr_2O_3	23.8	35 Cr_2O_3	23.8
14 Cr_2O_3	24.1	36 Cr_2O_3	19.5
15 Cr_2O_3	23.6	37 Cr_2O_3	22.6
16 Cr_2O_3	22.8	38 Cr_2O_3	23.1
17 Cr_2O_3	22.5	39 Cr_2O_3	24.05
18 Cr_2O_3	24.05	40 Cr_2O_3	22.5
19 Cr_2O_3	16.02	41 Cr_2O_3	22.1
20 Cr_2O_3	20.9	42 Cr_2O_3	26.0
21 Cr_2O_3	22.0	43 Cr_2O_3	23.0
22 Cr_2O_3	24.5	44 Cr_2O_3	21.1
		45 Cr_2O_3	29.8

Metallurgical Tests

Test runs on representative samples of these sands have been made at San Francisco, Denver and Seattle. A comparison of results indicates a recovery of from 70 to 75 per cent of the Cr_2O_3 contained in the original sands, in the form of a chromite concentrate averaging 40.45 per cent Cr_2O_3.

The San Francisco test was a table concentration at the laboratory of Hamilton, Beauchamp and Woodworth; Electromagnetic concentration at laboratory of University of California, Berkeley, California.

The sample was screened through a 40-mesh screen, the oversize being rejected. The material which passed through this screen was run on a Deister-Overstrom table, making two products—a tailing, which was rejected, and a rough concentrate. This rough concentrate was retabled, producing a middling and a finished table concentrate. The middling product was reserved for further treatment. The finished table concentrate was dried and run over a Wetherill magnetic separator, producing the final products of this test.

The Denver test was at the testing laboratory of Henry E. Wood.

The sample was screened through a 20-mesh screen, the oversize being rejected. The undersize was further screened through a 40-mesh screen, the oversize from this being likewise rejected. The 40-mesh material was run on a Wilfley table producing a tailing product, which was rejected, and a concentrate which was further treated on a Wetherill electro-magnetic separator.

The products from poles 1 and 2 were mixed to form the magnetite product, and 3 and 4 to form the garnet product. Pole 5 produced the chromite concentrate which analyzed as follows:

	Per Cent.
Cr_2O_3	41.35
SiO_2	4.10
Al_2O_3	13.05
FeO	24.58
Mn	1.64
Sulphur	0.81
TiO_2	Trace

Pole 6 gave a product consisting of a yellow sand (monazite) and chromite. The non-magnetic reject was further treated on a Wilfley table, producing thereby a tailing which was rejected and a concentrate consisting of zircon. Recovery of the chromite was shown to be 77.44 per cent.

The Seattle test was at the Laboratory of the U. S. Bureau of Mines experiment station.

The material was run over a half-size Deister-Overstrom concentrating table, forming three products—concentrate, middling and tailing. The concentrate and middling were run separately over Dings magnetic separators, forming in each case concentrate, middling, magnetite and sand products. The respective products from the two separations were of approximately the same grades, so were brought together, forming the final products of chromite, concentrate, middling, magnetite and sand. To this last (sand) was added the tailing product from the Deister-Overstrom table separation.

Proposed Method of Treatment

Based on the results of the foregoing tests, it is planned first to screen the sands and reject the 40-mesh oversize. The undersize will be concentrated on Deister-Overstrom tables, dried and then passed over a 3-magnet, six-pole Wetherill magnetic separator. The non-magnetic reject from the separator may be retabled and the zircon recovered.

Rejection of the 40-mesh oversize will, at the very beginning of the treatment, throw out about 8 per cent of the sands, without loss of valuable contents. Treatment on the Deister-Overstrom tables will further reduce the amount of material for magnetic separation. The concentrate leaving the table will be approximately 75 per cent, by weight, of the original sands and will contain 95 per cent of the chromite. The Wetherill magnetic separator treating the concentrate will recover over 75 per cent of the chromite. These chromite concentrates have been tested by the Huff Electrostatic Separator Co., and preliminary reports show that the grade can be improved to 46 per cent Cr_2O_3 or better.

The other products from the Wetherill separator will be magnetite, garnet and zircon (in the tailings).

Production

Since the total tonnage in the "Lagoon" is 25,000 tons, and a conservative estimate of the average Cr_2O_3 content is 20 per cent, a total of 5000 tons of Cr_2O_3 is obtained. Allowing 15 per cent loss in mining leaves 4250 tons and assuming a recovery of 70 per cent in milling, the amount is reduced to 2975 tons of Cr_2O_3. This is equivalent to 7437 tons of chromite concentrates averaging 40 per cent Cr_2O_3. There will also be about 4800 tons of garnet, 460 tons of magnetite and 288 tons of zircon produced. These chromite concentrates are particularly suited to the chemical trade, although the tenor of chromic oxide is not as high as in the imported ores. The rate of production should be from 300 tons to 400 tons monthly.

Unstable Conditions Delay Operations

Operations have been delayed owing to the unstable conditions affecting the chrome ore market. The lessee received direct encouragement from Government bureaus until very recently, when all support was withdrawn and the problem of finding a market for the product became the most important factor in the enterprise. Apparently the Government admits its moral obligation to protect domestic chrome ore producers who are left "holding the bag," but as yet no constructive action or policy is forthcoming.

Canadian Graphite Industry

HUGH S. SPENCE presents a short paper on "Canadian Graphite" in the recently issued Summary Report of the Mines Branch of the Canadian Department of Mines, 1917. He notes that the producing deposits occur in the Provinces of Ontario and Quebec within a radius of 150 miles of Ottawa. In spite of the great demand, but three companies operated at all steadily; nine others, each equipped with a mill, have been completely idle or in only intermittent operation.

The flake graphite occurs in disseminated form either in crystalline limestone or in calcareous bands intercalated in gneiss. Both varieties of ore have been treated by essentially similar concentration methods. These are, briefly, drying in wood-fired kilns, reducing in gyratory crushers followed by two or more sets of heavy rolls, and subsequent alternate screening and crushing in rolls of the flour-mill type. Each set of rolls eliminates gangue by reducing the brittle calcite and silicates to powder, while the soft graphite tends to flatten out and is caught by the screens. The product from the final set of rolls is sometimes polished between burr-stones or goes to an electrostatic machine, which removes any remaining impurities, particularly mica; the latter is one of the most difficult minerals to eliminate, owing to its softness and consequent resistance to crushing.

In the early days of the graphite industry, a wet process of concentration, employing buddles, was practiced. This method is still in use at one mill, as the initial step in concentration, followed by drying, the dried product then proceeding to rolls and screens.

While certain of the mills achieve a fair recovery of the graphite contained in the ore treated, the majority lose an undue percentage in the tailings. The concentration methods in general use are far from being efficient. In addition to poor recovery, the carbon content of the best, or No. 1, product is seldom brought over 90 per cent, and is generally lower; a great deal of the flake in the rock is broken up in the milling, and goes into the finer No. 2 product and to the No. 3, or dust. The large amount of dust produced in the mill in grinding the kiln-dried ore is very objectionable. Screen tests on samples of No. 1 flake from seven mills showed the mean percentages of different size flake composing this grade to be as follows:

	Per Cent
+ 20 mesh	1 7
+ 40 mesh	18 5
+ 60 mesh	67 0
+ 80 mesh	8. 0
+100 mesh	1 1
—100 mesh	2. 9

Most mills produce three grades of graphite, known as No. 1 flake, No. 2 flake and dust. The No. 1 flake goes principally to the crucible trade; No. 2 is employed in lubricating products; and No. 3, or dust, is used in foundry work.

The graphite particles employed in crucible manufacture are required to be of a certain size in order to bind efficiently with the clay. In this connection it may be noted that one of the reasons for the preference for Ceylon graphite for use in the manufacture of crucibles is that this variety does not occur in thin flakes like the American graphite, but is more massively crystalline and breaks up on crushing into more angular fragments, hence it requires less clay as a binder.

Minor Occurrences of Mercury in Europe

Comments on the Minor Quicksilver Operations in Austria, Italy, Spain and Mediterranean Countries—Mercurial Poisoning Cases Are Numerous, Due to a General Lack of Sanitary Precautions—Hygienic Measures Being Introduced at Idria

BY DR. ROLAND STERNER-RAINER[1]

IN ADDITION to the great mines at Almaden, Spain also possesses productive quicksilver deposits in the Asturian province of Oviedo, in Bajodez (Estremadura) and Granada (Andalusia), while the many others, even those of La Creu, have no commercial importance. To complete the list of mercury deposits the following must be mentioned, even though they are only of geological or mineralogical interest: Andra (Santander), in Teruel, Gargantiel (Ciudad Real) Torbiscon (Granada), Cartagena (Murcia), as also Purchena and Cuevas de Vera (Almeria).

Mieres, the center of the Asturian mining industry, (the quicksilver mines of the "Union Asturiana" and "El Provenir" or "Pena y Esperanza de Mieres" are situated here) lies on the railroad from Oviedo to Leon. These deposits, which at present are exploited in 24 mines, were worked by the Romans, but have been re-opened only since 1840. The ores are impregnations of cinnabar with a little metacinnabar, amalgam, orpiment and realgar, in the carboniferous breccias and quartzites.

The output, which in 1911 was 4699 tons of ore having an average content of 0.7 per cent, is treated in seven retorts, seven "Gascue-Rodriguez"[2] furnaces, and four of the old type of Idrian furnaces. Fifteen tons of mercury (formerly 50 to 80 tons) were produced. The impregnations found along this same railroad south of the Cordillera Cantabrica at Pola de Lena and Limares, and at the Rio Muno, are not of commercial importance.

The ores of Usagre Bienvenida in Bajadoz province (on the railroad from Merida via Zafra to Sevilla) are richer than those of Mieres. Here the cinnabar is associated with sulphide of copper ores, spathic iron and manganous carbonate, in quartz veins in the crystalline limestones of the Cambrian. This limestone also shows occasional cinnabar impregnations. Despite the fact that these deposits have been opened only a few years and that one of the new mines has doubled its former production of 1000 tons of ore per annum so that the future operation of these mines seems sure, two new Bustamente furnaces may be admired in full operation. The ore content, formerly 1.24 per cent, has increased, this fact explaining the relatively high output of 40 tons of mercury. Ores from the "Alpujarra," on the south slope of the Sierra Nevada, show a content of 0.7 to 2 per cent mercury. The mercury is contained in iron oxide incrustations of calcite; in certain places this oxide is so plentiful that two Bustamente furnaces were erected to treat it. In Valencia, all efforts to treat the ore profitably have failed; this ore consists of an intimate mixture of cinnabar, quartz and carbonate as vein fillings in the sandstone.

Even Portugal, which possesses no deposits of note, has produced small quantities of mercury during the last few years. The unexpected increase in production of the mines on the Appenine peninsula is due solely to the mines of Southern Toskana, at Siena Grosseto. The operations at Vallata, in the Province Belluno, have been abandoned for four years, while those of Levigliani and Ripa, in the Province Lucca, and those of Jano have been abandoned for 50 years.

Practically all the Italian production is from the region near Monte Amiata, and the operations of the live properties have been already described[3]. The mercury occurrences at Arcaja (Lucca), Monte delle Fate (Pisa), Monte Loreto (Gonova), San Quirico di Albaceto (Parma), Margna (Como) and San Donata (Cosenza) are of interest mineralogically, but are not exploited. The fine dust of lead smelter at Monteponi, Sardinia, yields a few hundred kilograms per annum.

Small Austrian and Hungarian Deposits

Austria possesses an even greater number of quicksilver occurrences than Italy, but here also the metal is found in quantity only at one locality. Idria, alone, is responsible for the country's production, all other mines being closed or never having been worked for cinnabar ores alone. Twenty years ago the plant of Littai in Krain was abandoned, which only shortly before had been producing 20 metric tons of mercury, and ten years later the neighboring plant of St. Anna, which was a rival of Littai in the '90s, followed suit. Sagron, in southeast Tyrol, which was exploiting the same ore body as the Italian Vallalta Company, has abandoned its mine and reduction plant since 1907. The best of the Dellach mines—Reichenau and Kotschna—as also that of the Buchholz mines near Paternion, have been abandoned for 60 or 70 years.

Since the decline of Russia's production[4] the only other European country producing quicksilver was Hungary, which produced about 80 tons. There are quite a number of quicksilver occurrences in Hungary, but at present the entire production comes from the Kotterbach plant in upper Hungary, where fahl ores are being treated. The Kotterbach mines also carry spathic and brown iron ore, through which small amounts of fahl ore are disseminated. The fumes formed in calcining these brown iron ores are passed into the bottom of limestone-filled, water-sprayed, wood condensers. Mercury, arsenic and antimony compounds and ore dust

[4] Since new ore bodies have been found in Nikitowka, the plant is being rebuilt.

are condensed to a slime carrying about 25 to 30 per cent mercury. This slime is filtered through coke, is washed and dried, and together with fahl ore, constitutes a charge containing 1.5 to 2 per cent mercury for two fine-ore furnaces. The rich soot of the furnace flues is pressed in the same manner as the furnace soot caught in the Cermak condensers, and the soot rejects are again charged to the fine-ore furnaces.

The quicksilver mine of Zalatna in Siebenbürgen is no longer productive, and the entire production of Hungary amounts to only 80 tons of mercury per annum.

There are several quicksilver prospects in Bosnia. Bosnic-Idria and Maschkara, however, are the only two that have produced any quicksilver (by a process resembling medieval metallurgy). To-day the developed ore bodies of these mines have been worked out. The promising quicksilver prospect of Avala which was discovered while grading for a railroad at a point about 25 km. south of Belgrade has also been worked out.

Deposits in Other Mediterranean Countries

Since none of the other European countries produce quicksilver—Prussia produces a few tons per annum from fine dust and lead chamber slime—there remain only the Mediterranean countries Algeria and Asia Minor to speak about. Even though these countries do not belong to Europe, they are closely related to it, both in historical development and economic relations. The Taghit mine, situated about 35 km. from the Algerian city of Batna, was one of the first to erect Cermak-Spirek fine-ore furnaces to treat their mixed ore, zinc blende and argentiferous galena containing cinnabar. Spirek also modified the coarse-ore shaft furnaces and the lead-treating reverberatory furnaces, so that they serve not only to roast the ores, but are at the same time adapted to the recovery of mercury.

Noticeable competition may soon be expected from the young mines of Asia Minor. The Anatolian ores found in a dry, high country not far from Koniah[5] were worked by the ancient Phrygians more than 3000 years ago. The knowledge of these prospects was lost in later times until the cinnabar was re-discovered by the chance find of a shepherd boy.

The ores are associated with local silicifications in the limestone, these silicifications being of contemporaneous deposition with the cinnabar. More than 13,000 tons of 1 per cent ore had been developed in these mines as long as five years ago. To furnace these ores the 15-ton Spirek shaft furnace and an 8-ton fine-ore furnace were erected.

Near the coast at Kara Burnu, about 30 km. south of Smyrna, large bodies of cinnabar-impregnated quartzites are found so near the surface that they can easily be mined by surface methods. The average ore mined during the first year of active mining operations ran 0.75 to 1 per cent mercury. The metallurgical plant consists of two Spirek shaft furnaces for lump ore and one fine-ore furnace. The capacity of the plant is 40 tons of ore per day, and the monthly production was 250 to 275 flasks of mercury.

One question always asked when quicksilver mining is mentioned is: "What influence does the reduction of mercury ores, the frequent contact with metallic mercury and the inhalation of the fumes of this metal exercise upon the human organism? What influence has this effect on the health of the workmen engaged in producing this metal, and to what degree has it been possible to eliminate or counteract these detrimental effects by improving the metallurgical practice and by social welfare work?"

The extensive literature on the subject of mercurial poisoning[6] shows that the symptoms of this poisoning are a swelling of the gums, a reddening and infection of the mucous membrane and the throat, excessive saliva flow and disorder of the digestive organs. Together with these ailments, the sick person experiences a dull feeling and exhibits a peculiar timidity which prevents him from working quietly while being watched. If the work around a quicksilver plant is not given up the infection of the mucous membrane develops ulcers in the mouth and causes a swelling of the saliva and lymphatic glands. The muscular control is also affected, resulting in a curious shaking of the body called tremor mercurialis, which may become so severe that those affected die from the fatigue it causes. The human organism when weakened from this disease is very apt to contract tuberculosis.

Mercurial Poisoning Frequent at Almaden

As might be surmised from the description of the conditions at Almaden, the cases of mercurial poisoning at this plant are very numerous. Not only the men in the reduction plant are exposed to this poisoning but also the miners in the poorly ventilated mines; this mercury vapor in the mines is due to the plentiful sprinkling of metallic mercury in the ore. If the number of fatalities at the plant is not large, this is because it is closed for about six months, in which time the workmen have opportunity partially to regain their health in the clear air of this elevated region. Even though the workmen three years ago appealed to the Government for a betterment of the hygienic conditions at the plant, and though professional men affirmed the itemized evils, little has been changed.[7]

The number of patients is still very great; even serious cases, such as "calambres," tremor, paralysis and ulcers which attack first the gums and then the jawbone are not rare. Wash bowls and baths are unknown at the plant. As noted, the miners are no less subject to mercurial poisoning than the reduction plant men, even though the latter are furnished with clothes made of a smooth material which are cleaned on company account. This is the sum total of the social welfare work, as there are no competent laws for the protection of workingmen and there is no inspector looking after the execution of such laws.

Tuscanian Conditions Better

The hygienic conditions in the Tuscanian works are very much better. The ore of the entire district contains no trace of free mercury, so that mercurial poisoning is not possible in the mining and drying of the ores.

[7] R. Velaz and José de Udeba: Informe sobre las minas de Almaden.

The individual plants are generally smaller, and because of the mild Italian climate, are airily built, assuring a frequent change of atmosphere in the buildings. The Abbadia San Salvatore plant, which was built only last year, incorporated hygienic principles in its construction and has numerous provisions for safeguarding the health of its workmen, only 25 per cent of whom are exposed to fume. Even so, as has been stated by C. D. Castro, not only are those exposed workmen subject to this occupational disease, but in time even those men who only handle the metallic mercury become sick. Careful instruction of the furnacemen would, no doubt, eliminate one source of the mercurial poisoning, but despite the most careful supervision by competent foremen, it was impossible to eliminate the carelessness of the workingmen. The clean-up, the treatment of the soot and the bottling of the mercury will always be dangerous as long as the present method of manipulation obtains, and the danger can only be minimized by the exercise of great caution on the part of all concerned.

Respirators which Tarngi[5] constructed of thin layers of aluminium netting were not successful at Abbadia San Salvatore, as this metal easily forms an amalgam with incidental tumifaction and development of heat. Frequent interchange of the men between the mines, reduction plant and outside working places is a beneficial, but not strictly adhered to, policy. Suitable working clothes, hot baths and frequent medical examinations, which are compulsory at Abbadia San Salvatore, prevent the development of serious cases of mercurial poisoning, and the occupational disease statistics of the plant are very encouraging since 1910.

Work in Idrian Mines Not Dangerous

The work in the Idrian mines, in which metallic mercury is found along with cinnabar, is not dangerous, as shown by statistics. The policy of changing the men who work in the stopes is strictly adhered to and adequate ventilation is obtained by improved methods. Light cases of sickness still occur, because the sense of cleanliness is but little developed in the workmen, and they do not make sufficient use of the bathing facilities provided at the plant. The change of workmen in the reduction plant, which has been reintroduced since 1897, has also bettered the conditions of health. Since the beginning of this century the amount of sickness has been further reduced by the technical improvements of the plant, and is now at the lowest known figure. Each workman is furnished with large rations of fat (as the eating of fat is thought to be beneficial), is furnished with suitable working clothes and enjoys an annual vacation of two weeks at full pay.

Light cases of poisoning are easily cured by a longer stay in a region of pure air. The introduction of producer-gas furnaces is a further step toward the fulfillment of hygienic requirements, as the soot production is less and consequently the work of the clean-up and of the soot treatment could be reduced appreciably. Kroupa's new shaft furnace will be a further step in this direction, as will the mechanical disposal of the furnace tailings, the improved condensers, the covered soot presses and the proposed new stack, all of which combine economical with hygienic advantages, and assure to Idria its position as the model quicksilver plant.

[5]Gazz. chim. ital. 34, II, p. 436.

Lately bathing facilities have been provided at the reduction plant also, and if occasional cases of sickness still occur, this will not be the fault of the health regulations of the plant, but will be due to the lack of good will on part of the workmen who carry out their assigned tasks without the proper sense of responsibility, neglect to use the shower baths, do not change their clothes, and by living in closed hot rooms allow the mercury of their clothes to vaporize. No amount of technical improvements or health regulations can change this; only a competent education of the workmen and their families for a period of many years can effect a complete remedy.

Engineering Research in Chemical Organizations

By Crosby Field

During the past four years the chemical industry in this country has been very rapidly advancing, having met with little opposition, but now, with the return of peace conditions, there is apparent the necessity for reorganizing to meet extremely intense competition, or as it may be called, "consolidating the positions in order to withstand heavy counter-attacks."

The parts to be played in this readjustment by finance, trade, commerce, export and other similar functions have been frequently discussed, and it is believed are now quite well understood, hence will not be mentioned further herein. There is one very useful "arm of the service," however, that it is believed is not quite so well understood, and it is the purpose of this article to invite attention to its activities and importance. For want of a more precise title, this function may be called "Engineering Research."

In any chemical organization there should be, of course, one research department, under the head of one man, who will be termed for the purpose of this article the manager of the research department. This department is divided into two branches, chemical and engineering, each under one man, who for the purpose of this article will be called a director; so that there should be a director of chemical research and a director of engineering research.

The functions of the director of chemical research are so well understood by the members of the chemical industry that further mention may be omitted and the remainder of this space devoted to a brief summary of the functions of the director of engineering research.

The director of engineering research has five principal functions to perform, which may be modified according to the particular organization in mind. These are (1) experimental, (2) compilation of engineering data, (3) standardization of layout and apparatus, (4) education and (5) liaison.

The experimental work necessary arises from two different causes, which, however, are interlocking, hence usually the same work produces both classes of results desired. These classes are the adaptation of chemical processes to factory conditions and the development of special chemical machinery.

The chemist usually develops his process in the chemical laboratory, using grams of chemicals in glass apparatus, dealing only superficially with the physical characteristics of the intermediates and of the final

product and neglecting all matters concerning the quantities of energy required and the best method of transmission thereof. The process is then put into the factory using hundreds or even thousands of pounds instead of grams and metal or wooden apparatus instead of glass, when the physical characteristics of the products and of their containers become vital, the impurities collected in the process assume greater importance, and the economy of the process frequently depends upon the method of supply and transmission of the energy required. It is because of such conditions that processes seemingly good in the laboratory fail in the factory; and conversely, processes which appear good in the laboratory, but which involve many questions to which the factory answers are not known, fail to be tried out in the factory because of the heavy expense at stake.

The general answer to the above situation is a function of the director of engineering research, and to accomplish his object he has an engineering or factory laboratory. This is a building equipped with small apparatus similar in all respects to the apparatus which is standard in the factory and of such size as to give accurately the necessary physical constants. This will generally be found to require units having a capacity of several gallons, or about one hundred pounds. The interior of the building will generally be without permanent structures, with the exception of a number of columns, to which beams may be quickly clamped, so as to facilitate the setting up and the tearing down of apparatus.

Will Adapt Chemical Process to the Laboratory

Within this laboratory will be accomplished the adaptation of the chemical process to the factory. The chemist will turn over the complete results of his experiments with grams of material within glass tubes to the director of engineering research, who in this laboratory will determine the proper apparatus to be used, and in connection with the director of manufacturing, the approximate sizes thereof. He will be responsible for deciding the material of which the apparatus shall be made, whether direct fire, steam or oil will be used for heating, the utilization of waste gases. limits of and methods of engineering control, etc. In some organizations he will be responsible for designing the plant, but if not he is to turn over to the design engineer the necessary data and the proper recommendations for types of apparatus.

In order to accomplish the above it is necessary that he perform well his second function, that of collection of engineering data. To do this he may either utilize the factory organizations or send agents to run special tests, or both. He must have available, however, not only the basic facts regarding each type of machinery present in the plant or advertised on the market, but also operating records of cost, including maintenance and consumption of power, in so far as possible. This should apply not only to the process apparatus in the plant, that is to say, what is more generally called the chemical machinery, but also the plant machinery, by which is meant all that directly connected with the power plant, including boilers, engines, refrigerators, gas producers, compressors and vacuum pumps, pumps, elevators and conveying machinery, etc. Having collected these data, the third function, that of standardization of machinery, follows as a matter of course.

In all these three functionings situations will arise which indicate the necessity or desirability of a new type of special chemical machinery, which should then be developed in the engineering laboratory. It is thought that this will become very important in the near future, as a stabilizing of the chemical industry throughout the world will tend to establish standard chemical processes, after the establishment of which manufacturing success will depend in greater degree upon the development and adoption of special machinery.

Function of Education Frequently Overlooked

The fourth function, education, is a matter frequently overlooked. The training of the necessary personnel for a new industry is always hard, but is vital to the success of that industry. It is essential that it be recognized as a necessary function, and its place included in the several branches of the organization where opportunity is afforded for its performance.

The director of engineering research should, therefore, publish to a selected list of trustworthy employees such of his accumulated data as would appear desirable. This can well be done by means of a mimeographed periodical, which should be kept up to the minute by containing the results of the latest tests, especially acceptance tests on new installations. He should also provide for lectures and the other well-recognized methods of disseminating information, but by far his greatest opportunity lies in his laboratory during the time that a chemical process is being adapted to the factory. The operating foreman-to-be and his principal assistants should be present during the experiments, and this small unit production should be continued for a while under the actual operation of these men, directed by the engineering laboratory specialist in charge.

The fifth function, liaison, is the most difficult to perform satisfactorily, and will be the one, in the last analysis, which will cause the director to succeed or to fail. Close touch must be had with all departments and with all plants, and this contact must be maintained in spite of the many pet theories and frequently crotchety characters of the various executives and men concerned. The director must so limit his activities to the strictly engineering and advisory sides that in his dealings with the chemist, particularly while the process is still in the chemical laboratory, the latter will have no suspicion of his motives and will render him full information and his further co-operation during the period the process is in the engineering laboratory. Many good suggestions will be forthcoming from men in the plants, and a system should be arranged for giving recognition to the individual.

In short, there is present to-day in each chemical company of any considerable size the necessity for a director of engineering research, who must perform his major functions of engineering experiments, compilation of engineering data, standardization of layout and apparatus, education and liaison with energy and tact. He should, furthermore, be a man of considerable executive ability, engineering experience and knowledge of chemistry, and should, moreover, have linked with those no small degree of inventive talent.

Roasting Flotation Concentrates.—CHARLES H. FULTON of Cleveland, Ohio, patents a process of roasting fine flotation concentrates by burning them in heated air somewhat similar to the way pulverized fuel is consumed. Fig. 1 shows an approved system of apparatus. The inventor notes the difficulties of proper desulphurization of fine concentrators in mechanically rabbled hearth roasters. In case the concentrates are roasted

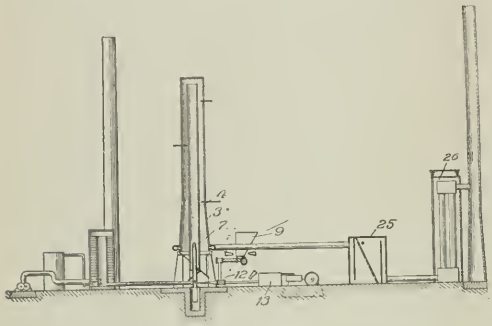

FIG. 1. APPARATUS FOR ROASTING FLOTATION CONCENTRATES

in a current of hot gases of combustion, the coarser particles fall out of suspension partially oxidized, while the fine particles are carried along in suspension in gases too cool for proper reaction. In Fig. 1 preheated ore is supplied from hopper 9 to casting 12, where the proper amount of compressed air from receiver 13 is mixed with it to hold the particles in suspension pending their delivery through injector nozzle 7. At this point it meets low pressure air heated in the gas-producer-stove system illustrated to the left, the various temperatures being so regulated that ignition takes place immediately. The temperature of the preheated air of combustion evidently depends upon the temperature of the ore, the length of the furnace in which complete combustion is to be effected, and the calorific power of the fuel. The burned ore travels up the inner stack 4 and down the outer annular portion 3, the bulk of it being deposited in the hoppers at the bottom of the vertical shaft. Fine dust is caught in the chamber 25 and the electrostatic precipitator 26. If the minimum air for proper roasting is introduced at the ore burner the resulting gas will be very high in sulphur dioxide and may be utilized in the manufacture of sulphuric acid. (1,273,844; assigned to Metallurgical Laboratories, Inc.; July 30, 1918.)

Smelting Copper-Nickel Pyrrhotite.—W. MCA. JOHNSON of Hartford, Conn., patents the following process of smelting copper-nickel pyrrhotites so that a separation of the valuable constituents may be made. Such an ore may contain 2 per cent copper, 4 per cent nickel, 45 per cent iron, 38 per cent sulphur, and 0.10 oz. gold, silver, platinum and palladium. This ore is roasted, smelted in the blast furnace and converted into a matte containing 52 per cent nickel, 26 per cent copper, and 1 per cent iron in well-known machines and in the usual manner. The resulting matte is cupola-melted with 45 per cent crude Na_2SO_4, a large excess of coke and a strongly reducing atmosphere. The sodium sulphate is reduced to the sulphide, which dissolves copper sulphide more readily than nickel, and the result is a regulus containing "tops" rich in copper and "bottoms" rich in nickel. The process is repeated two or three times, when the tops are finally low in nickel and the bottom low in copper, and contain 95 per cent Ni_2S, 2 per cent Na_2S, 1.5 per cent Cu_2S, 1 per cent Co_2S and 0.5 per cent FeS. The bottoms are then granulated and treated with chlorine gas at 250 deg. C., converting the sulphides to chlorides and volatilizing the sulphur as SCl_2. Water leaching will now remove the soluble sulphides, leaving a residue which may be smelted for silver. All metals but nickel, iron and cobalt may now be removed by electrolysis, precipitation by H_2S in acid solution, or cementation on nickel or iron. The latter is preferred, and gives a precipitate of copper, platinum and palladium which is readily separated by known methods. From the nickel-iron-cobalt solution the two latter may be precipitated by bleaching powder and Na_2CO_3, the resulting hydrates being filtered and separated by redissolving and reprecipitating the iron by a quantitative amount of the same reagents. The nickel chloride solution is now contaminated by sodium chloride only, and is evaporated to dryness, fused, and when at a red heat steam and pulverized coal are introduced into the bath. The nickel is then reduced according to the equation

$$NiCl_2 + H_2 = Ni + 2HCl$$

and melted to ingot form in an open hearth furnace. (1,238,298; assigned to the Continuous Zinc Furnace Co.; Aug. 28, 1917.)

Potash From Silicates.—GUY STERLING of Salt Lake City, Utah, notes that a heated mixture of potassium bearing silicates and sodium sulphate will produce but little soluble potash unless the amount of sodium salt is largely in excess. High temperature will volatilize some of the potash, but vitrifies the residue so that the remainder of the potassium cannot be extracted by lixiviation. If, however, a mixture of approximately three parts of feldspar, two parts of limestone and one part of sodium sulphate or chloride is heated with stirring at about 800 deg. C., the potassium in the silicate is displaced in part by the sodium and in part by the calcium oxide, and the potassium sulphate formed by the reaction volatilizes and escapes with the CO_2 formed by the simultaneous decomposition of the limestone. Thus the limestone is usable as a chemical reagent, as a preventive of vitrification, and its liberated gas is a vehicle for the escape of the volatile potash salts. (1,268,508; June 4, 1918.)

Reducing Reagent.—CHARLES S. BRADLEY of New York City heats burned lime with pyrite to a low red heat, when the following reaction will proceed to within 10 per cent of completion:

$$4FeS_2 + 4CaO = 4FeS + 3CaS + CaSO_4$$

This mixture may be used as such for the reduction of ferric or cupric salts, the reaction going forward strongly in hot solutions:

$$14CuCl_2 + 4FeS + 3CaS = 7Cu_2Cl_2 + 4FeCl_2 + 3CaCl_2 + 7S$$

Similarly for ferric chloride. The calcium chloride is of value as a solvent, while any copper sulphide contained in the original pyrite not only aids the reaction but goes into solution and is recovered at the same time. (1,253,775; Jan. 15, 1918.)

Recent Chemical and Metallurgical Patents

Alumina for Refractories and Abrasives

Crystalline Fused Alumina.—F. J. TONE of Niagara Falls patents a process of treating ores of alumina containing alkali, such as alunite, so as to recover the alumina in fused crystalline form and the alkali in water-soluble compounds. He charges the ore into an electric arc furnace of the depending electrode type, such as he patented in No. 929,517, and heats it to a temperature in excess of 2100 deg. C. This drives off all the moisture, sulphur and potassium of the alunite without forming any double silicates of potassium and aluminium which result from low-temperature calcination. The fume may be caught in well-known apparatus. The crystalline product remaining in the furnace is free from potash, and should contain from 95 to 99 per cent alumina. In case the ore contains more iron and silica than will permit of a product of this required purity, the impurities may be reduced to a 20 per cent ferrosilicon during the process of fusion by the addition of the required iron and reducing elements. (1,239,984; assigned to the Carborundum Co.; Sept. 11, 1917.)

Beta-alumina.—L. E. SAUNDERS and R. H. WHITE of Niagara Falls note that small amounts of beta-alumina have been noted in certain furnace products. It is so termed to differentiate it from alpha-alumina, occurring naturally as corundum, sapphire, ruby, etc., the two forms being distinguished by the lower refractive index, higher double refraction and lower specific gravity of the beta modification. It also has a characteristic platy, hexagonal crystalline habit, and is hard but relatively weak. It has special applications for abrasives which polish without leaving scratches. If substantially pure amorphous alumina be heated with somewhat more than five per cent of Na_2O as alkaline carbonate, the resulting pig will be found to contain from 70 to 85 per cent of the alumina in the beta modification. The alkaline compound must be chosen which will not be largely volatilized during the heating, since the alkaline oxide is probably the converting agent. The inventors think that the alkali additions yield a product of high boiling point which exists as vapor at the moment of solidification of the alumina, as evidenced by the cellular appearance of portions of the resulting pig. The effect of the alkali additions is seriously interfered with by SiO_2 and TiO_2, and the raw materials must be substantially free from these harmful compounds. (1,263,708; assigned to Norton Co.; Apr. 23, 1918.)

Alumina from Impure Bauxite.—In case an impure bauxite containing after calcination about 4 per cent SiO_2, 7 per cent Fe_2O_3 and 3.5 per cent TiO_2 is melted in a furnace such as patented in re-issue No. 13,027 with 2 to 3 per cent Na_2O, a dark gray, fine-grained product is produced. Messrs. SAUNDERS and WHITE find that this product has a weak grain desirable for certain purposes. Carbon may be introduced before furnacing, which will produce material lighter in color, and with a smaller amount of the original and added impurities. In either case will any considerable amounts of beta-aluminium be formed. (1,263,709 and 1,263,-710; asigned to Norton Co.; Apr. 23, 1918.)

Purifying Alumina.—If impure bauxite be heated with carbon in an electric furnace with an idea of forming crystalline material for refractories or abrasives, considerable alumina is reduced if the amount of carbon added approaches the theoretical quantity required to reduce the impurities. The tendency to form reduction products from the carbon of the furnace electrodes or bottom is very pronounced in fusing even the purest alumina, since the easily reducible oxides of iron and silica existing as normal impurities protect the alumina to a certain extent. L. E. SAUNDERS and R. H. WHITE of Niagara Falls have discovered that the reduced alumina, consisting of undesirable carbides and hypothetical sub-oxides which disintegrate when exposed to moisture, may be preserved from disintegration by adding to the furnace charge an appropriate amount of sodium or zinc compounds (from 1 to 5 per cent) and any excess of which volatilizes from the fused mass. The formation of undesirable weak, porous grains of alumina from these oxidizing additions may be obviated, together with a substantial absence of reduced aluminium compounds, by adding from 10 to 20 per cent of iron to the furnace charge. The molten iron absorbs the excess carbon and the reduced impurities and does not react with the fused alumina. Another method of refining alumina containing carbides is to mix it with impure bauxite similar to that forming the original charge. The quantity of impure material used should be such that the reduced aluminium compounds will react quantitatively with the iron, silicon and other oxides on a second heating. This method is particularly good, since it is believed that the reduction products of alumina are the effective reducing agents for the elimination of the last traces of non-aluminous oxides. (1,269,141, 1,269,222, 1,269,223 and 1,269,224; assigned to Norton Co.; June 11, 1918.)

Production of Magnesium.—G. O. SEWARD of Jersey City, N. J., patents an improvement to No. 935,796 for the manufacture of metallic magnesium. It consists of electrolyzing molten chlorides of magnesium and potassium, using a carbon anode and a cathode of molten tin or copper. The magnesium separated from the electrolyte is alloyed with the molten cathode, which is removed when it contains sufficient magnesium for further treatment. In the second step the magnesium alloy is used as anode, the electrolyte is of the same nature as before, except with the addition of a heavy salt of an electropositive metal such as barium chloride. In the second electrolysis, magnesium enters the solution from the impure anode and deposits on the cathode, so arranged that the magnesium separated may float upon the electrolyte. The tin or copper remaining at the end is much more easily purified of the silicon, iron and calcium ordinarily present than is the formerly-used aluminium, while the magnesium resulting is not harmed by the traces of copper or tin contained. (1,258,261; assigned to American Magnesium Corporation; Mar. 5, 1918.)

Synopsis of Recent Chemical and Metallurgical Literature

"Nicu" Steel and Its Manufacture.—A paper advocating a radical revision in metallurgical practice as applied to the Sudbury nickel ores was read before the Montreal Metallurgical Association at the April, 1918, meeting, by G. M. COLVOCORESSES of Humboldt, Ariz. He noted the fact that Sudbury produced 85 per cent of the world's nickel, of which 75 per cent was added to open-hearth furnaces to produce nickel-steel. At the same time, 650,000 tons of iron valued at 14 million dollars contained in the Sudbury ores are slagged and wasted annually. Present metallurgical practice on nickel ores closely parallels copper smelting up to the production of a white metal containing 80 per cent combined nickel and copper, which converter product is further refined and separated by either the Orford or the Mond process. Available details of the mining and metallurgy of such ores are given fully in the excellent 1917 Report of the Royal Ontario Nickel Commission. Consideration of the average analysis of Sudbury ores given in Table I leads to the conclusion, however, that the ore is one of iron, and should be treated accordingly.

New Caledonia ships a garnierite ore, essentially a hydrous silicate of nickel and magnesium (Table I, which is ordinarily mixed with a sulphide ore for matte smelting. In 1880 some of this ore was locally smelted in a small blast furnace to a "fonte" or impure nickel pig, containing 66 per cent nickel and 24 per cent iron, but the process was not successful owing to a variety of reasons, including the difficulty of preventing considerable sulphur entering the pig from impure coke. More recently, however, this ore has been smelted with iron ores in the electric furnace and the best nickel-steel produced. The process bids fair to become standard for the treatment of this peculiar material.

Recent developments of the multiple hearth roaster have enabled one to dead-roast sulphide ores, using a relatively small amount of extraneous fuel to reduce the sulphur from 3 to 4 per cent to 0.3 to 0.5 per cent. Properly mixed with a flux, the calcine may be delivered in a nodulized condition suitable for blast furnace smelting. The coming of the electric furnace has also enabled the metallurgist to reduce the sulphur in steel made from fairly impure materials to any reasonable amount. Evidently, then, the Sudbury ores could now be roasted and smelted direct, were it not for the universal prejudice existing against any alloy steels containing copper. This is in spite of such results as were obtained in 1909 by Burgess and Aston, who concluded that copper would replace nickel satisfactorily to a certain extent in low carbon alloy steels. Clamer also experimented carefully and took out patents on a method of smelting roasted copper-nickel matte with iron ores into a satisfactory alloy steel. Monel scrap (containing 70 per cent Ni, 27 per cent Cu) has been extensively used in place of pure nickel in the manufacture of alloy steels which have sold under the name of "nickel-steel," withstanding successfully various physical tests, and being manufactured into armor-piercing shells and high grade automobile parts.

Sjostedt and Ulke of the Lake Superior Corporation (operating at the "Soo" in 1901) first worked on the production of ferro-nickel from Canadian ores. "Nicu" steel has been made in laboratory furnaces for several years, and in commercial quantities in a leased plant in East Montreal during the fall of 1917. A low grade ore was used which had been mined for some 20 years, and meantime had weathered, oxidized and disintegrated. This was roasted to 0.4 per cent S in a coal fired reverberatory heating furnace, hand rabbled. It was then charged to a 6-ton Heroult tilting furnace, six or eight charges of the following composition being required to make a heat:

1400 pounds calcine
535 pounds burned lime
375 pounds coke breeze.

Slag was poured at intervals, and the resulting pig, of the analysis given in Table I, refined in an open-hearth furnace of the standard type. No particular extra expense or trouble was encountered in this last operation; 72 tons of steel were made, and subjected to a wide variety of tests demonstrating it to be apparently equal to nickel-steel whose Ni content equalled the Ni + Cu in the "Nicu" steel.

TABLE I—ANALYSES OF VARIOUS NICKEL-COPPER PRODUCTS

Element	Average Sudbury Ore	New Caledonia Garnierite	Weathered Ore Smelted	Pig Iron Produced	Steel Made
Ni	3.25	5	1.3	2.2	2.13
Cu	1.7	..	0.28	0.4	0.4
Fe	40.0	10	46.0	....	....
S	25.0	..	8.0	0.09	0.03

The author presents cost data which lead to the conclusion that under 1916 conditions "Nicu" steel equivalent to a 3 per cent nickel-steel (selling at $60) can be produced in quantity at $30 per ton, scrap being figured at $16 per ton. The process recovers 98 instead of the present 80 per cent of the nickel in the ore, 98 instead of 83 per cent of the copper, and 96 per cent instead of none of the iron. The increased saving if applied to all Sudbury ores would amount to $41,000,000, which is practically equal to the present returns. In commercial operation on a large scale, the nodulized calcine would be mixed with iron-silicate slags and iron ores and smelted to an alloy pig containing 0.2 per cent sulphur. The molten pig would be charged directly to the refining furnace, where a basic slag would remove the bulk of the remaining sulphur and the composition could be carefully adjusted to specification.

Size of Grog in Fire Clay Bodies.—In Technologic Paper No. 104 of the Bureau of Standards F. A. KIRKPATRICK discusses the effect of the size of grog upon the strength and other properties of fire clay bodies. The grog was made by crushing and sizing high-grade fire brick to the following fractions: 4 to 8 mesh, 8 to 12, 12 to 20, 20 to 40. 40 to 80, and 80 to dust. Various combinations of these fractions were then made, proportioned with 50 per cent by weight of plastic fire clay ground through 20 mesh, and molded by hand into briquets 1 x 1 x 7 in. Seven series of mixtures were studied, sufficient work being done to construct tri-axial diagrams showing lines of equal strength, porosity, etc.

Unburned briquets were air dried three days, then one day at 65 deg. C. and two days at 110 deg. Seven briquets of each mixture were broken in a transverse bending machine and the modulus of rupture averaged to give a value for strength. The porosity was determined by immersing in kerosene for 12 hours at 0.2 atmosphere and determining the increase in weight. The tri-axial diagrams representing the modulus of rupture for the various mixtures show isō-strength lines. Some of the series were not coördinate in results for porosity and strength, which phenomenon the author explains thus: The porosity of briquets made of large grog is less than those containing moderately fine particles because the larger particles are more dense than an equal weight of packed smaller ones, and also because the voids were increased by a mixture of grog-sizes. The strength of certain of these mixtures, however, varies directly instead of inversely with the porosity (which latter is the general rule for ceramic materials) because in these cases the larger particles of grog gave weaker bodies due to a lack of bond and contact between clay and grog, causing small cracks in drying. These cracks were the finer with fine aggregates of grog. If the ratio of size and shape of the voids in clay-grog bodies is such that the smaller particles do not fit into the voids but separate the larger bodies, then there will be no areas of maximum strength or density appearing in the corresponding tri-axial diagrams. As above noted, a mixture of sizes giving the maximum density by packing into the voids left by each larger size gives the highest strength.

In mixtures where half the fire clay was replaced by Georgia kaolin the corresponding briquets decreased 60 per cent in strength. When the fire clay was totally replaced by Illinois kaolin, however, corresponding mixtures showed less bonding power with coarse grog but very much more with fine grog than had the pure fire clay. Mr. Kirkpatrick notes that the kaolin was of putty-like consistency, while the fire clay was sticky and contained more colloidal matter. Therefore, kaolin should be expected to make weaker—less dense—mixtures. However, kaolin evidently had certain percentages of grains fitting into the voids between the finest grog, giving with these more dense and stronger bodies. The author concludes that the size of grain of the bond clay has as much effect as that of the grog. Since the size of grain of clay cannot be directly determined in the present state of our knowledge of disperse systems, systematic experimentation such as is done in this publication appears to be the only method of determining the best mixtures for strength and other physical characteristics.

Burned briquets were tested in three series: one burned two hours at 1200, another at 1250 and the third at 1300 deg. C. After burning, the briquets were tested for strength in bending. In these tests the average difference from the mean value was about 10 per cent. Burned briquets were also tested for porosity, volume shrinkage and resistance to sudden temperature changes. In the latter test six pieces of each composition were heated to 600 deg. C. and quenched in ice water five times in succession, the modulus of rupture was determined, and the percentage diminution computed. The number of quenchings to produce failure seems to be no criterion for small pieces, but the author determined that a standard brick should resist from two to three times as many quenchings as the 1 x 1 x 7 in. briquets.

The test results show an erratic relation between porosity (or shrinkage) and strength. The conclusion is that the porosity should not be taken as a criterion of strength in a burned brick, because its effect is often overridden by other factors. However, the relation betwen the "surface factor" of the grog and the strength of the briquet plots as a straight line (except for regions of large grog sizes) for all three heat treatments and is therefore an accurate index of the strength. The rate of gain in strength increases with temperature of burning, since the rate of solution of the finer particles is more rapid. The coarser grog mixtures stood the quenching tests best, and since the results at 600 deg. C. closely agree with those at 1000 deg., the lower and more readily handled temperature is recommended for such work. A grog furnished by a large maker of refractories approximated closely one of the mixtures giving a maximum strength, showing that a good surface factor can be had in practice by careful attention to the crushing system.

Effect of Dielectric Deposits on Cottrell Operation.—E. R. Wolcott in the *Physical Review*, Vol. 12, p. 284, notes that early experience with certain Cottrell plants developed the baffling fact that after operation for a few hours the potential difference between electrodes was lowered to such a degree that the designed power input could not be carried below a safe amperage. This phenomenon occurred in plants treating a non-conducting fume, like sulphur. He therefore investigated the effect of various substances interposed in the gap between a spark and plate, and re-established the previously known facts that the sparking potential is greater if the point is negative for gaps larger than 2.3 mm. (being $2\frac{2}{3}$ times as great at 6 cm.); that the voltage required to start a spark is greater than that necessary to maintain it; and that the voltage required to arc a considerable amperage is higher than that producing a snappy spark consuming a very small amount of power. In addition he found that introducing dielectrics into the gap produced changes in the arcing voltage varying as their nature, continuity, surface condition and position. By careful adjustment a silent glow was produced and photographed, showing it to emanate from the edge of a perforation in a piece of paper resting on the plate. Edges or perforations in thin sheets of mica and glass and a very thin deposit of flowered sulphur or sintering-machine dust was sufficient to lower the arcing voltage approximately one-half.

The roughened, porous or discontinuous surface accumulates a charge sufficient to ionize the surrounding gas, producing the typical glow of the positive discharge and increasing the conductivity of that portion of the gap. No lowering of the sparking voltage results when this charge is conducted away, such as is done by precipitated moisture or by a superimposed grounded screen.

Reinforced Waterproof Paper

Arthur D. Little, Inc., of Cambridge, Mass., have perfected a cotton cloth reinforced waterproof paper which will soon be placed on the market. Heavy grades as strong as burlap such as packing house concerns use for heading barrels of provisions will also find special use in making packages for various chemicals.

Book Reviews

TECHNICAL CHEMISTS' HANDBOOK. By *George Lunge*, Ph. D. Flexible leather, duodecimo (12 x 18 cm.), 264 pages; price $3.50 net. New York: D. Van Nostrand Company.

The second edition of this well-known handbook. It is brief, condensed, and the data well chosen. The analytical methods cover the manufacture of heavy inorganic chemicals only, and not metallurgy, inorganic chemistry, or the finer chemical products. In each case only the best, standard method is given, "in order to avoid discrepancies." It can thus be seen that the spirit of the work is eminently practical, and not one of scientific precision.

HANDBOOK OF OIL ANALYSIS. By *Augustus H. Gill.* Pages 210. Price $2.50. Philadelphia: J. B. Lippincott Co.

The excellent handbook of oil analysis by Dr. Gill has now reached an eighth edition. This bespeaks in striking terms its widespread usefulness in the arts with which it deals. The additions and changes noted in this edition cover a description of the new McMichael viscometer and tests on lubricating oils, some revision of special oils and greases, and methods of the analysis of edible and hardened fats and oils have been brought up to date. For a handy, condensed and competent book on the analysis of oils, this book is to be recommended for a laboratory text book and ready reference.

ORGANIC COMPOUNDS OF ARSENIC AND ANTIMONY. By *Gilbert T. Morgan, D. Sc.*, Professor of Applied Chemistry, City and Guilds Technical College, Finsbury, London, England. Longmans, Green & Company, 1918. 8vo., 376 pp. Price $4.80 net.

The appearance of such an excellent monograph as Professor Morgan's will be welcomed, not only by those to whom the work will be useful, but by all chemists who derive a certain amount of satisfaction in knowing that an important special field of research has been mapped in a thorough manner.

It is a pity that our universities, burdened as they are financially, are practically unable to subsidize or otherwise encourage their professors to write scientific works other than Outlines, Introductory Courses, General Principles etc., such as underpaid and overworked professors are in the habit of writing in order to buy bread and beans for themselves and their families. Professor Morgan's excellent book is therefore most unusual. The thought even suggests itself that the trustees of the City and Guilds College of Finsbury, London, must have had their attention diverted by something, perhaps the war, or they might have seen to it that Professor Morgan did not have "leisure" or "spare time" to write such a book.

It seems to the reviewer that Professor Morgan's book embodies all the features which an excellent scientific monograph should. It contains an excellent bibliography and discusses all of the earlier work which is important, including particularly the work of Bèchamp. The author uses structural formulae freely, which greatly facilitates following the chemical changes involved in what are fairly complex substances. The subject is brought practically up to date, that is up to the end of 1917. The author naturally gives considerable attention to atoxyl and its derivatives and the developments which led to the discovery and application of salvarsan, neosalvarsan, luargol, gallyl etc. While the details of the preparation of many of these compounds are given, it might have been pointed out that the successful preparation of many of them requires a degree of skill and experience such as comparatively few organic chemists attain.

The chemistry of the organic compounds of antimony places this series of compounds with those of arsenic and Professor Morgan has dealt with them in the same thorough manner as the arsenic derivatives, although the latter have proven of much greater value to the physician.

The clinical results of many thousands of cases are given which indicate the latest results of clinical practice with all of the more important derivatives, including the newest. While evidently intended primarily for chemists, the book will undoubtedly prove of value and interest to physicians as well.

Personal

MR. C. E. LEN. ARNOLD, formerly with the Inspiration Consolidated Copper Co., at Inspiration, Ariz., has accepted a position with the Consolidated Arizona Smelting Co. at Mayer, Ariz.

MR. JAMES CHESTER ASHBY, who has been instructor in chemistry at Lehigh University, South Bethlehem, Pa., for some time, is now with the Buffalo Works of the National Aniline & Chemical Co. in the research laboratory.

MR. F. D. BAKER, who has been with the Colorado Department of the American Smelting & Refining Co. for twenty years as chief designing and construction engineer, retired Jan. 1, 1919. Mr. Baker will continue work in a limited consulting practice at Denver, Colo., with his sons.

MR. CHARLES Y. CLAYTON, recently with the Department of the Interior, Bureau of Mines, Pittsburgh, Pa., has become connected with the Missouri School of Mines, Dept. of Metallurgy and Ore Dressing, Rolla, Mo.

PROF. G. H. CLEVENGER is now with the National Research Council, Washington, D. C., having completed the research work at Colorado Springs for the U. S. Bureau of Mines.

MR. W. M. CORSE, who was general manager of the Titanium Bronze Co., Niagara Falls, N. Y., has accepted a position as manufacturing engineer with the Ohio Brass Co., Mansfield, Ohio.

DR. R. W. HESS has recently accepted a position as senior research chemist with the National Aniline & Chemical Co., Buffalo, N. Y. He was formerly chemist in the dyestuff department of the Chicago plant of the Sherwin-Williams Co.

DR. T. POOLE MAYNARD, Atlanta, Ga., has been made Southern representative of the Research Corporation of New York.

MR. LOUIS O. MONROE has assumed duties as manager of sales and chief engineer for the Clarage Fan Co., Kalamazoo, Mich. Previous to entering the service he was in charge of the Chicago office of the same company.

MR. H. C. PARMELEE, editor of CHEMICAL & METALLURGICAL ENGINEERING, has returned from a two-months' visit to England and France, where he was the guest of the British Government.

MR. A. J. PHILIPPS is now research chemist with the Aetna Explosives Co., Emporium, Pa. He was formerly chief chemist of the Western Alkali Refining Co.

MR. FREDERICK A. SCHEFFLER has become associated with the Fuller Engineering Co. and will make his headquarters at the company's New York office, 50 Church St., Mr. Scheffler was formerly indentified with the Babcock & Wilcox Co.

MR. K. B. THOMAS has resigned his position Jan. 1, 1919, as superintendent of the sulphuric acid department for the Calumet & Arizona Mining Co., Douglas, Ariz., to become associated with the Standard Chemical & Oil Co. of Troy, Ala., as its superintendent.

MR. HORACE N. TRUMBULL, who has recently received his discharge from the Engineers Officers' Training School at Camp A. A. Humphreys, Va., has been appointed advertising manager of the Wellman-Seaver-Morgan Co., of Cleveland, Ohio. Before entering the service, Mr. Trumbull was advertising manager of the S.K.F. Ball Bearing Co., Hartford, Conn.

MR. F. L. WOODS has been appointed superintendent of the Tygert-Allen Works at Philadelphia, Pa., of the American Agricultural Chemical Co., of Weymouth, Mass. He was formerly assistant superintendent of the Bradley fertilizer works of the same company at Weymouth.

Obituary

MR. THOMAS G. BROWN, of Denver, Colorado, died at Lluvia de Oro, in Chihuahua, Mexico, on November 19 of pneumonia following influenza. He was 31 years of age and was graduated from the Golden School of Mines in 1907. After graduation he spent some time in Colorado, being employed at the Tomboy and other mines. In 1910 he joined the staff of the Mines Company of America and was employed at both the Dolores mine, in Chihuahua, and the Creston-Colorada, in Sonora, for a number of years. In April, 1917, he became assayer and chemist for the Lluvia de Oro Gold Mining Co., and in that capacity he was serving at the time of his death.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, Jan. 11.—There has been no buying on any large scale up to date this year. In several cases there have been declines in prices, which are certain to rapidly reach a peace basis. Manufacturers will not order their metal supplies before orders for their product are booked.

Aluminium:—The Government prices on ingots 98 to 99 per cent Al are $660 a ton f.o.b. plant in 50-ton lots; $662 down to 15-ton lots; and $666 down to 1-ton lots, which prices will continue the remainder of the year. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

Antimony:—Large stocks of antimony are being held at prices ranging from 7¾ to 8c. per lb.

Copper:—Prime lake is nominal at 23c. Electrolytic is selling at 20¾c. and casting at 19c. The producers are determined to hold their prices high believing that the foreign demand will soon be strong.

Copper sheets, hot rolled	lb.	$0.33 —$0.35
Copper sheets, cold rolled	lb.	.34 — .36
Copper bottoms	lb.	.41 — .43
Copper rods	lb.	.33 — .35
Copper wire	lb.	.23
High brass wire	lb.	.24¼— .26¾
High brass sheets	lb.	.24¼— .26¾
High brass rods	lb.	.23¾— .25¾
Low brass wire	lb.	.26¾— .28¾
Low brass sheets	lb.	.26¾— .28¾
Low brass rods	lb.	.27¼— .29¾
Brazed brass tubing	lb.	.35¾— .37¾
Brazed bronze tubing	lb.	.40¼— .42¼
Seamless copper tubiog	lb.	.35 — .37
Seamless bronze tubing	lb.	.37 — .39
Seamless brass tubing	lb.	.34 — .36
Bronze (gold) powder	lb.	1.00 — 1.75

Tungsten:—Tungsten took a decided decline with best grade scheelite $18.00 and wolframite $16.00.

Zinc:—Spelter continues to decline, spot New York bring $156 to 157 per ton; East St. Louis, $148 to 150, February, $147 and March, $146. Sheet and plate zinc is quoted at 13c. per lb. and prime metallic powder, 14c. lb.

OTHER METALS

Bismuth	lb.	$3.50 — $3.65
Cadmium	lb.	1.50 — .....
Cobalt	lb.	2.50 — 3.50
Magnesium	lb.	1.75 — 2.10
Mercury	75 lb.	110.00 — .....
Mercury	lb.	1.95 — .....
Nickel	lb.	.40 — .45
Tungsten	lb.	34.00 — .....
Iridium	oz.	175.00 — .....
Palladium	oz.	135.00 — .....
Platinum	oz.	105.00 — 108.00
Silver	oz.	1 01⅛— .....

Lead:—Buyers are not taking much interest in lead at present. East St. Louis prices are from $112 to $114 per ton; New York, 5¾ to 6c. lb.; sheet lead is 9c. lb.

Tin:—The tin market is divided into two sections: Government 72½c. tin and outside lots at 70½ with an expected decline to 68c. per lb.

The Iron and Steel Market

Demand for iron and steel since the signing of the armistice has pursued a somewhat different course than was generally expected. Instead of the sudden cessation of hostilities producing a sudden slump in demand with a sharp curtailment in production, to be followed by an early pick-up in demand, the reverse has been the case. For several weeks after the signing of the armistice there was no plethora of steel although production was very well maintained, while now, in the middle of January, steel mill operations are decreasing and there is only a very meager demand.

Production of steel ingots in December was at the rate of 43,750,000 tons a year, showing actually an increase over the November rate, which was 43,000,000 tons a year, not counting time out for celebration of the armistice, while the maximum rate ever attained was 46,800,000 tons, last September. The December rate represented about 90 per cent of capacity, which may be taken at 49,000,000 tons a year. Mills are operating at various rates, but the average seems to be only about 65 per cent, and in view of the lightness of demand a 50 per cent rate is far from impossible in the near future. A 50 per cent rate on present capacity would represent approximately as large an output as was made in any calendar year prior to 1912, so that it really would represent a great deal of steel after all.

PRICES

There is no question about pig iron and steel prices, in face of the light demand. They are strictly maintained, in accordance with the reductions that were made in accordance with the schedule prepared by the Institute committee for presentation to the War Industries Board at the meeting of December 11. The board did not receive the schedule, but the iron and steel industry was keen and efficient to accept and adopt the suggestion. Broadly speaking, the reductions were $3 on pig iron, $4 on unfinished steel and $4 to $7 per net ton on finished products.

It is the lightness of demand that dispels any question about the maintenance of these slightly reduced prices, which are, of course, about double the ten-year pre-war average. There is no incentive on the part of producers to cut prices, slightly or heavily, for there will be more buying for a time at established prices than there would be in a disorganized market, and further cuts could hardly be made without precipitating demoralization. The time will come when it will be advantageous for the producers to bargain with buyers, when the buyers appear in such force as to show that price really counts. At the present time buying is of purely hand to mouth character.

The present demand, such as it is, does not represent new buying in any considerable measure, but rather, in the case of pig iron, the acceptance of shipments against old contracts, and in steel products the placing of specifications or shipping orders against old contracts. In steel products the contracts are, as is well understood, but little more than options given the buyer, who specifies or not as he desires. For this reason steel is being furnished under old contracts at the reduced prices, the mills readily making the necessary adjustments with customers. Even the sheet manufacturers, who adopted the "binding form" of contract a couple of years ago, have made these adjustments. The blast furnaces, which make firm contracts, not option-contracts such as obtain in the steel trade, are as a rule making the $3 concession to customers.

CHARACTER AND DEMAND

By far the heaviest steel demand at present is from the automobile trade, which will probably use more steel than ever during the next few months. The Emergency Fleet Corporation is taking a considerable tonnage, but its re-

quirements are scaled down from the rate that obtained in the closing months of the war, as there is a large accumulation of steel, more than a million tons, to be worked off. Jobbers are buying and specifying moderate tonnages, requiring very prompt deliveries in all cases and being quite unwilling to commit themselves as to the future. Much the same policy obtains with ordinary manufacturing consumers. There is practically no demand for steel for regular construction jobs, buildings, bridges, factories, power stations and the like, nor is there any evidence that such demand will develop in the near future.

There is some cleaning up of orders for railroad steel, very little in rails, but a fair tonnage in car and locomotive material. There is no new business in sight in railroad steel, and a comprehensive program of railroad buying cannot of course be formulated until it is determined what is to be done with the railroads. Congress will take its own time in that matter.

Throughout the iron and steel trade the prediction is still made freely and with confidence that there is in store a period of several years of great activity. It is likewise admitted that the period will not begin for a while yet, a period of readjustment intervening. Apparently this readjustment is expected to proceed under its own steam and its own guidance. It does not seem to be regarded as anybody's business to help the readjustment along or even to study the subject. One branch of this readjustment, however, must properly be left to circumstances. There must be awaited a dying out of the wave of bolshevism in Europe, and certain psychological reactions in the minds of workingmen in the United States, whereby they will become disposed to regard a job as an asset and become willing to render a day's service for a day's wage.

Chemical Market

COAL-TAR PRODUCTS:—Although there is a continued dullness in the coal-tar product market, it would seem that more than the ordinary seasonable quietness is prevailing, to such an extent that many of the items that come under this heading are almost at a standstill. At the present it is too early in the year to have had any material effect, although there is a strong undertone evident and inquiries in the trade for export purposes have been quite active, but the shipping situation is generally considered the handicap for extensive trading in this direction. It is believed, however, that as soon as this condition develops to be easier a splendid business will set in. Toluol is now in easy supply, with phenol being freely offered in the market at some unheard of prices, but producers appear to be in a position to keep benzol in a firm condition, although stocks on hand are plentiful.

Toluol:—Resale offerings of this product are made at 5c. below the manufacturer's price, while quotations from first hands are firm at the recent decline.

Phenol:—The material has developed to be the most unsettled product of the crudes. Producers are making price concessions with no favorable results and the offerings through second hands, which are 10c to 15c below the manufacturer's prices, seem to originate no buying interest.

Benzol:—This product is subject to no pressing call; however, it is held in strong hands and prices are firmly maintained.

Phthalic Acid:—The item is being produced in more liberal quantities and therefore the additional demand that has been in evidence during the recent period has not affected the situation to any noticeable extent. Manufacturers' prices are quotably unchanged for the crude or the anhydride.

Acid Sulphanilic:—Dealers are looking forward to some activity for this material, which has been considerably neglected, and no price revisions have taken place in view of this feeling.

Aniline Oil:—Up to the present writing there has been no price change reported for this product, which continues in light demand.

Aniline Salt:—Price concessions are being made by manufacturers and dealers, but consumers are seemingly purchasing only for immediate needs. Stocks in the various directions are in sufficient quantities to take care of additional business.

Benzaldehyde:—The routine demand that is in evidence for this product is well taken care of, as supplies in the market are now considerably easier and there has been a general decline in prices.

Benzidine:—Buyers are still holding off and the only business of importance that is passing is for the base material, while the sulphate seems to be considerably neglected and manufacturers have made some substantial downward revisions in prices.

HEAVY CHEMICALS:—Actual business in heavy chemicals during the interval has been of moderate proportions. However, the holiday season passed and the inventory period nearing completion seems to be a source of satisfaction throughout the trade, although there are no indications of any immediate activities and it is generally believed this will not take place until conditions are more favorable for export purposes. In the meantime most of the items that come under this heading have been subject to a decline in prices, with only the medicinal products holding firm. Caustic soda and soda ash, the barometers of the heavy chemicals, have again come in for a trying period and weak holders play havoc with the market.

Caustic Soda:—The tone of this market has been decidedly easier during the latter period of the past week with buyers' views considerably below the market prices, which have declined from 10c. to 20c. per hundred pounds. The 76 per cent solid product from the warehouse was available at $3.30 per hundred pounds, while ex-dock quotations range from $3.20 to $3.30, according to seller. Dealers during the latter part of the week were not disposed to offer f.a.s. owing to the unsettled conditions with labor at the docks. Ground caustic appears to be subject to no important call and was offered at from $4.25 to $4.50 per hundred pounds.

Soda Ash:—There is no indication of any immediate activity for any of the various packings and during the week light ash in hardwood barrels appears to have been the only one of the items subject to any call and this was for no pronounced quantity. Bags from the warehouse were quoted at from $1.90 to $2.00 per hundred pounds, while material rolling was offered at $1.80 New York. Double bags at Middle Western shipping points were held at from $2.40 to $2.50, while material in regular barrels was quoted at $2.30 to $2.45 ex-warehouse and hardwood barrels were offered at $3.35 f.a.s. Dense ash in barrels was held at $3.50 f.a.s., and on the Pacific Coast offerings were heard at $3.60 ex-warehouse.

Bleaching Powder:—Resale material has been rather difficult to dispose of; however, export drums appear to be the only item that has been subject to any noticeable call, while domestic drums are being more freely offered. At Niagara large domestic drums were quoted at $1.90, while first hands were holding at 2c per pound and 3¼c seems to be the general asking price for export drums, while in the resale market offerings were made at 3c to 3⅛c.

Bichromate of Potash:—Most dealers continue to quote 37c to 38c per pound for this material, for which manufacturers report a satisfactory call, but the consuming demand is not pressing and stocks are in sufficient quantities to take care of additional business.

Bichromate of Soda:—A fair inquiry prevails for this material both for export and domestic consumption. First hands report stocks in reasonable quantities and are quoting 18c to 18½c, while in the resale market frequent lots appear and sales are passing at from 17c to 17½c per pound.

Cyanide of Soda:—Most dealers continue to quote the 96 to 98 per cent product at from 30c to 31c per pound, while the chloride mixture of 73 to 76 per cent is held at 25c to 27c per pound and the chloride carbonate mixture is offered at from 20c to 21c. Movement is of no important character and only the routine business is in evidence.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET JAN. 10, 1919

Acetic anhydride	lb.	1.00	—	1.25
Acetone	lb.	.25½	—	.25½
Acid, acetic, 28 per cent	cwt.	5.00	—	5.50
Acetic, 56 per cent	cwt.	8.50	—	9.50
Acetic, glacial, 99½ per cent, carboys	cwt.	19.00	—	19.20
Boric, crystals	lb.	.13¾	—	.15

Aluminium sulphate, technical	lb.	.02½	—	.02½
Aluminium sulphate, iron free	lb.	.04¼	—	.04½
Ammonia aqua, 26 deg., carboys	lb.	.08¾	—	.09
Ammonia, anhydrous	lb.	Nominal		
Ammonium carbonate	lb.	.12	—	.13
Ammonium nitrate	lb.	(Fixed Price)		.15
Ammonium, sulphate domestic	gal.	.07½	—	.08
Amyl acetate	lb.	5.30	—	5.35
Arsenic, white	lb.	.11	—	.13
Arsenic, red	ton	.65	—	.70
Barium carbonate, 99 per cent	ton	80.00	—	90.00
Barium carbonate, 97-98 per cent	ton	65.00	—	67.00
Barium chloride	lb.	65.00	—	75.00
Barium sulphate (Blanc Fixe, Dry)	lb.	.04½	—	.05
Barium nitrate	lb.	.11½	—	.12
Barium peroxide, basis 70 per cent	lb.	.30	—	.32
Bleaching powder, 35 per cent chlorine	lb.	.02	—	.03½
Borax, crystals, sacks	ton	.08¼	—	.08¼
Brimstone, crude	lb.	65.00	—	70.00
Bromine, technical	lb.	.75	—	...
Calcium, acetate, crude	lb.	.04	—	.05
Calcium, carbide	ton	.12	—	.14
Calcium chloride, 70-75 per cent, fused, lump	lb.	22.00	—	24.00
Calcium peroxide	lb.	1.50	—	1.70
Calcium phosphate	lb.	.22	—	.23
Calcium sulphate, 98-99 per cent	lb.	.09	—	.09½
Carbon bisulphide	lb.	.08	—	.09
Carbon tetrachloride, druma	lb.	.15	—	.16
Carbonyl chloride (phosgene)	lb.	1.10	—	1.50
Caustic potash, 88-92 per cent	100 lb.	.62	—	.65
Caustic soda, 76 per cent	lb.	3.30	—	3.50
Chlorine, liquid	lb.	.10	—	.12
Cobalt oxide	lb.	1.60	—	1.65
Copperas	lb.	.01½	—	.02½
Copper carbonate	lb.	.30	—	.31
Copper cyanide	lb.	.75	—	.78
Copper sulphate, 99 per cent, large crystals	lb.	.09	—	.09½
Cream of tartar, crystals	100 lb.	.63	—	.68
Epsom salt, bags, U.S P	lb.	2.75	—	...
Formaldehyde, 40 per cent	lb.	.21½	—	.22
Glauber's salt	lb.	.02	—	.02½
Glycerine, bulk, C.P	lb.	.20	—	.21
Iodine, resublimed	lb.	4.25	—	4.30
Iron oxide	lb.	.06	—	.08
Lead acetate, white crystals	lb.	.17	—	.17½
Lead arsenate (Paste)	lb.	.15	—	.18
Lead nitrate, C. P.	lb.	.85	—	.86
Litharge, American	lb.	.12	—	.14
Lithium, carbonate	lb.	1.50	—	2.05
Magnesium carbonate, technical	lb.	.16	—	.17
Nickel salt, single	lb.	.14	—	.15
Nickel salt, double	lb.	.12	—	.13
Phosgene (see Carbonyl chloride)	lb.	1.10	—	1.50
Phosphorus, red	lb.	1.00	—	1.15
Phosphorus, yellow	lb.	.85	—	1.10
Potassium bichromate	lb.	.38	—	.40
Potassium bromide granular	lb.	1.25	—	1.26
Potassium carbonate calcined, 85-90 per cent	lb.	.38	—	.40
Potassium chlorate, crystals	lb.	.38	—	.40
Potassium cyanide, 98-99 per cent	lb.	.60	—	.70
Potassium iodide	ton	3.75	—	3.80
Potassium muriate, 80-85 p. c. basis of 80 p. c	lb.	300.00	—	350.00
Potassium nitrate	lb.	.27	—	.31
Potassium permanganate, U. S. P	lb.	1.30	—	1.50
Potassium prussiate, red	lb	2.30	—	2.50
Potassium prussiate, yellow	ton	.80	—	.90
Potassium sulphate, 90-95 p. c. basis 90 p. c	lb.	Nominal		
Rochelle salts	lb.	46½	—	.48
Salammoniac, gray gran	lb.	.19	—	.20
Salammoniac, white gran	100 lb.	.16	—	.17
Sal soda	ton	1.40	—	1.65
Salt cake		18.00	—	20.00
Silver cyanide, based on market price of silver	oz.	...	—	...
Silver nitrate	oz.	.63½	—	.64
Soda ash, 58 per cent, light, flat (baga)	100 lb.	1.95	—	2.00
Soda ash, 58 per cent, dense, flat	100 lb.	3.35	—	3.50
Sodium acetate	lb.	.18½	—	.20
Sodium bicarbonate, domestic	lb.	.02¾	—	.03
Sodium bicarbonate, English	lb.	...	—	...
Sodium bichromate	lb.	.17½	—	.18½
Sodium bisulphite, powd	lb.	.12	—	.14
Sodium chlorate	lb.	.18	—	.20
Sodium cyanide	lb.	.30	—	.35
Sodium fluoride, commercial	lb.	.16	—	.17
Sodium hyposulphite	lb.	3.10	—	3.50
Sodium molybdate, per lb. of Mo	lb.	2.50	—	...
Sodium nitrate, 95 per cent	100 lb.	4.42	—	4.55
Sodium nitrite	lb.	.19	—	.20
Sodium peroxide	lb.	.35	—	.45
Sodium phosphate	lb.	.04	—	.04½
Sodium prussiate, yellow	lb.	.34	—	.36
Sodium silicate, liquid (60 deg.)	lb.	.03	—	.04
Sodium sulphide, 30 per cent, crystals	lb.	.02	—	.03
Sodium sulphide, 60 per cent, fused	100 lb.	.05	—	.06
Sodium sulphite	lb.	.05½	—	.06
Strontium nitrate	lb.	.25	—	.30
Sulphur chloride, druma	lb.	.07½	—	.09
Sulphur dioxide, liquid, in cylinders	lb.	.15	—	.40
Sulphur, flowers, sublimed	100 lb.	4.35	—	4.50
Sulphur, roll	100 lb.	3.70	—	3.85
Sulphur, crude	ton	65.00	—	70.00
Tin bichloride, 50 deg	lb.	.28	—	.29
Tin oxide	lb.	.90	—	1.00
Zinc carbonate	lb.	.18	—	.20
Zinc chloride	lb.	.15	—	.15½
Zinc cyanide	lb.	Nominal		
Zinc dust, 350 mesh	lb.	.13½	—	.14
Zinc oxide, American procesa XX	lb.	.10½	—	.12
Zinc sulphate	lb.	.04¼	—	.06¼

Coal Tar Products (Crude)

Benzol, pure, water white	gal.	22	—	27
Benzol, 90 per cent	gal.	25	—	...
Toluol, in tank cars	gal.	25	—	...
Toluol, in druma	gal.	30	—	35
Xylol, pure, water white	gal.	45	—	55
Solvent naphtha, water white	gal.	18	—	25
Solvent naphtha, crude, heavy	gal.	12	—	15
Creosote oil, 25 per cent	gal.	45	—	55
Dip oil, 20 per cent	gal.	35	—	40
Pitch, various grades	ton	8.00	—	20.00
Carbolic acid, crude, 95-97 per cent	lb.	Nominal		
Carbolic acid, crude, 50 per cent	lb.	Nominal		
Carbolic acid, crude, 25 per cent	lb.	Nominal		
Cresol, U. S. P	lb.	18	—	.20

Intermediates, Etc.

Alpha naphthol, crude	lb.	1.00	—	1.10
Alpha naphthol, refined	lb.	1.50	—	1.60
Alpha naphthylamine	lb.	.55	—	.60
Aniline oil, drums extra	lb.	.27	—	.30
Aniline salts	lb.	.40	—	.42
Anthracene, 80 per cent	lb.	6.00	—	...
Benzaldehyde (f.f.c.)	lb.	4.25	—	4.50
Benzidine, base	lb.	1.45	—	1.60
Benzidine, sulphate	lb.	1.15	—	1.25
Benzoic acid, U. S. P	lb.	1.90	—	2.15
Benzoate of Soda, U. S. P	lb.	1.75	—	1.90
Benzyl chloride	lb.	2.45	—	2.50
Beta naphthol benzoate	lb.	10.00	—	12.00
Beta naphthol, sublimed	lb.	.75	—	.85
Beta naphthylamine, sublimed	lb.	2.65	—	...
Dichlor benzol	lb.	.15	—	.20
Diethylaniline	lb.	3.25	—	4.00
Dinitro benzol	lb.	.36	—	.38
Dinitrochlorbenzol	lb.	.39	—	.41
Dinitronaphthaline	lb.	.55	—	.60
Dinitrotoluol	lb.	.40	—	.50
Dinitrophenol	lb.	.49	—	.50
Dimethylaniline	lb.	.70	—	.73
Diphenylamine	lb.	1.00	—	1.10
H-acid	lb.	2.85	—	3.10
Metaphenylenediamine	lb.	1.85	—	2.05
Monochlorbenzol	lb.	.16	—	.19
Naphthalene, flake	lb.	.09	—	...
Naphthalene, balls	lb.	.12	—	.12½
Naphthionic acid, crude	lb.	1.20	—	1.30
Naphthylamin-di-sulphonic acid	lb.	1.00	—	1.10
Nitro naphthaline	lb.	.45	—	.50
Nitro toluol	lb.	.55	—	.60
Ortho-amidophenol	lb.	6.00	—	7.00
Ortho-dichlor-benzol	lb.	.15	—	.20
Ortho-toluidine	lb.	1.00	—	1.10
Ortho-nitro-toluol	lb.	.75	—	.85
Para-amidophenol, base	lb.	4.25	—	...
Para-amidophenol, H. C. L	lb.	4.25	—	5.00
Para-dichlor-benzol	lb.	.15	—	.20
Paranitraniline	lb.	1.50	—	1.70
Para-nitro-toluol	lb.	1.50	—	1.60
Paraphenylenediamine	lb.	3.25	—	3.50
Para toluidine	lb.	2.25	—	2.50
Phthalic acid anhydride	lb.	3.25	—	3.50
Phenol, U. S. P.	lb.	.20	—	.30
Resorcin, technical	lb.	4.50	—	5.00
Resorcin, pure	lb.	7.00	—	8.00
Salicylic acid U. S. P	lb.	.77	—	.85
Salol	lb.	1.50	—	2.00
Sulphanilic acid, crude	lb.	.31	—	.33
Toluidine	lb.	2.50	—	3.00
Toluidine-mixture	lb.	1.00	—	...

Petroleum Oils

Crude (at the Wells)

Pensylvania	bbl.	4.00	—	...
Corning, Ohio	bbl.	2.85	—	...
Somerset, Ky	bbl.	2.60	—	...
Wooster, Ohio	bbl.	2.68	—	...
Indiana	bbl.	2.28	—	...
Illinois	bbl.	2.42	—	...
Oklahoma and Kansas	bbl.	2.25	—	...
Caddo, La., light	bbl.	2.25	—	...
Corsicana, Tex., light	bbl.	2.25	—	...
California	bbl.	1.24	—	1.57
Gulf Coast	bbl.	1.35	—	...
Mexican	bbl.	1.90	—	...
Fuel Oil				
New York	gal.	15	—	...
Philadelphia	gal.	10¼	—	...
Baltimore	gal.	.07½	—	.15
Pittsburgh	gal.	.07½	—	10½
Texas	bbl.	1.85	—	2.35
Los Angeles	bbl.	1.65	—	...

Gasoline (Wholesale)

New York, motor	gal.	.24½	—	....
Gas machine	gal.	.41½	—	....
72-76 degrees	gal.	.33½	—	.39½
70-72 degrees	gal.	.32	—	.37½
67-70 degrees	gal.	.30½	—	.36½
Pittsburgh, motor	gal.	.25½	—	....
Chicago, motor	gal.	.22½	—	.23
Oklahoma, motor	gal.	.21½	—	....
San Francisco, motor	gal.	.20½	—	....

Paraffine Waxes

Crude, 103 to 105 deg. m.pt.	lb.	.08½	—	.09
Crude, 118 to 120 deg. m.pt.	lb.	.09½	—	.10
Crude, 124 to 126 deg. m.pt.	lb.	.10	—	....
Refined, 120 deg. m.pt.	lb.	.13½	—	....
Refined, 128 deg. m.pt.	lb.	.14	—	....
Refined, 135 deg. m.pt.	lb.	.16	—	.16½
Ozokerite, brown	lb.	.75	—	.80
Ozokerite, green	lb.	.85	—	.90

Lubricants

Black, reduced, 29 gravity, 25-30 cold test	gal.	.24	—	.25
Cylinder, light	gal.	.45	—	.50
Cylinder, dark	gal.	.39	—	.43
Paraffine, high viscosity	gal.	.40	—	.41
Paraffine, 0.903 sp. gr.	gal.	.36	—	.38
Paraffine, 0.885 sp. gr.	gal.	.26	—	.28

Flotation Oils

(Prices at New York unless otherwise stated)

Pine oil, crude, f. o. b. Florida	gal.	.44	—	....
Pine oil, steam-distilled, sp. gr. 0.925-0.940	gal.	.58	—	.60
Pine oil, destructively distilled	gal.	.58	—	.60
Pine-tar oil, sp. gr. 1.02-1.035	gal.	.35	—	....
Pine-tar oil, double refined, sp. gr. 0.965-0.990	gal.	.42	—	....
Pine-tar oil, ref., light, sp. gr. 0.950, tank cars, f.o.b. works	gal.	.37	—	....
Pine-tar oil, ref., heavy, sp. gr. 1.025, tank cars, f.o.b. works	gal.	.28	—	....
Pine-tar oil, ref., thin, sp. gr. 1.060-1.080	gal.	.32	—	....
Turpentine, crude, sp. gr. 0.870-0.900	gal.	.45	—	....
Hardwood oil, f.o.b. Michigan, sp.gr. 0.960-0.990	gal.	.23	—	....
Hardwood oil, f.o.b. Michigan, sp.gr. 1.06-1.08	gal.	.23	—	....
Wood creosote, ref., f.o.b. Florida	gal.	.31	—	....

Naval Stores

Rosin A-E barrel	280 lb.	14.37	—	14.50
Rosin F-I	280 lb.	14.50	—	15.25
Rosin K-N	280 lb.	17.00	—	17.60
Rosin WG-W	280 lb.	17.60	—	18.00
Spirits of turpentine	gal.	.66	—	.77
Wood turpentine, steam distilled	gal.	.64	—	.65
Wood turpentine, destructively distilled	gal.	.58	—	.60
Pitch	bbl. 200 lb.	8.00	—	....
Tar, kiln dried	280 lb.	13.00	—	13.50
Retort tar	280 lb.	14.00	—	14.50
Rosin oil, first run	gal.	.77	—	....
Second run	gal.	.80	—	....
Third run	gal.	.85	—	....
Fourth run	gal.	.95	—	....

Vegetable Oils

Castor oil	lb.	.26	—	.28
China wood oil	lb.	.22	—	.24
Cocoanut oil	lb.	.16	—	.21
Corn oil	lb.	.18	—	....
Cottonseed oil, crude	lb.	.17½	—	.22
Linseed oil, raw, cars	gal.	1.81	—	1.86
Palm	lb.	.18	—	.23
Peanut oil, crude	lb.	.17½	—	....
Soya bean oil, Manchuria	lb.	.16½	—	....

Glues

Extra white	lb.	.31	—	.35
Cabinet	lb.	.25	—	.26
Brown foot stock	lb.	.15	—	.19
Fish glue, 50-gal. barrels	gal.	1.00	—	1.50

Miscellaneous Materials

Barytes, floated, white, foreign	ton	Nominal		
Barytes, floated, white, domestic	ton	33.00	—	36.00
Beeswax, white, pure	lb.	.63	—	.65
Beeswax, unbleached	lb.	.43	—	.48
Blanc fixe	lb.	.05½	—	....
Casein	lb.	.17½	—	.30
Ceylon graphite	lb.	.07½	—	.25
Chalk, light, precipitated, English	lb.	.04½	—	.06
China clay, imported, lump	ton	20.00	—	40.00
China clay, domestic, lump	ton	15.00	—	22.50
Feldspar	ton	8.00	—	12.00
Fluorspar, gravel, f.o.b. mines	ton	28.00	—	40.00
Fluorspar, washed, powdered	ton	90.00	—	....
Fuller's earth, powdered	100 lb.	1.50	—	2.00
Japan wax	lb.	.26	—	.27
Mexican graphite	ton	60.00	—	75.00
Madagascar graphite	lb.	.10	—	.15
Orange shellac	lb.	.72	—	.80
Pumice stone	lb.	.04	—	.08
Red lead, dry, carloads	100 lb.	11½	—	11½
Soapstone	ton	15.00	—	25.00
Stearic acid, 120 deg. m.pt.	lb.	.13	—	.14
Stearic acid, 140 deg. m.pt.	lb.	.18	—	.19
Talc, American, white	ton	20.00	—	40.00
White lead, dry	lb.	.14	—	.14½

Refractories, Etc.

(F.O.B. Works)

Chrome brick	net ton	175.00	—	....
Chrome cement	net ton	75.00	—	....
Clay brick, first quality fireclay	per 1000	50.00	—	55.00
Clay brick, second quality	per 1000	35.00	—	40.00
Magnesite, raw	ton	30.00	—	35.00
Magnesite, calcined, powdered	ton	50.00	—	65.00
Magnesite, dead burned	net ton	50.00	—	60.00
Magnesia brick, 9x4½x2½	net ton	110.00	—	125.00
Silica brick	per 1000	50.00	—	60.00

Ferroalloys

Ferrocarbontitanium, 15-18 per cent, carloads, f.o.b. Niagara Falls, N. Y.	ton	200.00	—	250.00
Ferrocerium	lb.	15.00	—	30.00
Ferrochromium, per lb. of Cr	lb.	.30	—	.40
Ferromanganese, domestic, 70 per cent basis	ton	220.00	—	....
Ferromanganese, English	ton	325.00	—	....
Spiegeleisen (16-18%)	ton	67.50	—	....
Ferromolybdenum, per lb. of Mo	lb.	3.50	—	4.50
Ferrosilicon, 75 per cent, f.o.b. N. Y.	ton	....	—	....
Ferrosilicon, 50 per cent, contract	ton	143.00	—	....
Ferrotungsten, 75-85 per cent, f.o.b. Pittsburgh	lb.	Nominal		
Ferrouranium, f.o.b. works, per lb. of U	lb.	7.50	—	....
Ferrovanadium, f.o.b. works	lb.	....	—	....

Ores and Semi-finished Products

Chrome ore, 45 per cent minimum, f.o.b. Cal. per unit	ton	1.50	—	1.55
Chrome ore, 43 per cent and over, New York, per unit	ton	1.40	—	....
Coke	ton	6.00	—	7.00
Manganese ore, 48 per cent and over, per unit	ton	1.20	—	....
Manganese ore, chemical	ton	80.00	—	100.00
Molybdenite, per lb. of MoS_2	lb.	1.25	—	1.50
Tungsten, Scheelite, per unit of WO_3	ton	25.50	—	....
Tungsten, Wolframite, per unit of WO_3	ton	23.00	—	....
Uranium oxide, 96%	lb.	3.25	—	3.60
Vanadium pentoxide, 99%	lb.	10.50	—	....
Pyrites, foreign	unit	.17	—	....
Pyrites, domestic	unit	.28	—	.30½

Plant Supplies

BUILDING MATERIALS

Common clay bricks	M	13.00	—	14.00
Hollow tile, 4x12x12	M	60.00	—	....
Hollow tile, 12x12x12	M	170.00	—	....
Lime	ton	16.50	—	....
Portland cement	bbl.	2.59	—	....
Single glass (82-lb.), 10x26-16x24		21.00	—	27.00
Double glass (164 lb.), 10x26-16x29		31.00	—	39.00
Yellow pine lumber	M	39.00	—	45.00
Fir lumber	M	38.00	—	53.00
Hemlock	M	24.50	—	40.00
Tarred felt (14-lb. sq.)	ton	68.00	—	....
Roofing pitch	ton	27.00	—	....
Asphalt coated roofing (35-55-lb.sq.)	sq.	1.60	—	2.45
Slate surfaced asphalt shingles	sq.	5.25	—	5.50
Corrugated galvanized iron	ton	109.00	—	127.00
Putty	100 lb.	6.25	—	....
Red oxide (Ppte. Copperas)	100 lb.	15.00	—	20.00
Native red oxide	100 lb.	3.25	—	8.00
Red metallic paint	100 lb.	1.20	—	1.50
White lead in oil	100 lb.	15.00	—	16.00
Red lead in oil	100 lb.	12.28	—	14.50
Zinc oxide (dry)	100 lb.	13.00	—	14.50
Zinc oxide—leaded	100 lb.	9.00	—	10.00
Yellow ochre	100 lb.	1.50	—	10.00
Ultra marine blue	100 lb.	14.00	—	50.00
Prussian blue	100 lb.	135.00	—	150.00
Chrome green	100 lb.	40.00	—	70.00
Paris green	100 lb.	43.00	—	49.00
Mineral black	100 lb.	1.75	—	2.25
Powdered bone black	100 lb.	5.50	—	12.00
Lampblack	100 lb.	15.00	—	45.00
Gas carbon	100 lb.	16.00	—	25.00
Mexican petroleum pitch	100 lb.	1.00	—	2.00
Gilsonite	100 lb.	2.00	—	2.50
Coal tar pitch	100 lb.	.60	—	1.25

STRUCTURAL IRON

Blue annealed sheet iron	ton	78.00	—	85.00
Black sheet iron	ton	94.00	—	100.00
Galvanized iron	ton	121.00	—	125.00
Tern plate, 8-lb. coating	ton	150.00	—	....
Tern plate, 15-lb. coating	ton	177.50	—	....
Tern plate, 25-lb. coating	ton	200.00	—	....
Tern plate, 40-lb. coating	ton	240.00	—	....
Tin plate, prime	ton	155.00	—	....
Tank plates	ton	60.00	—	....
Beams, channels, angles, T's, Z's	ton	56.00	—	....
Rivets	ton	88.00	—	92.00
Steel pipe, ¾ to 3-inch	ton	51.00	—	....

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

DUNDEE—The Dundee-Arizona Copper Co. will build a treatment plant. A. J. Smith, secretary.

JEROME—The Shea Copper Co. will build its own concentrator in 1919. D. J. Shea, manager.

WALKER—The Black Diamond Mining & Development Co. will build a milling plant at its properties. C. N. Brown, manager.

Arkansas

MORRILLTON—The Commissioners of Sewer District No. 2 have awarded the contract for the construction of a sewer, involving 15,900 lin. ft. pipe, septic tank, etc., to S. R. Morgan & Co., Little Rock. Estimated cost, $16,000.

California

BISHOP—The Montezuma Mines will install a concentrator for water and oil flotation concentration at its mine about six miles east of Big Pine. Estimated cost, $30,000. A. Del Mar, superintendent.

LOS ANGELES—The Globe Grain & Milling Co., 901 East 3rd St., has awarded the contract for the construction of two 40 x 80 ft. and 40 x 60 ft. concrete buildings at 51st St. and Santa Fe Ave., for a hydrogen and oxygen plant, to Leonordt & Peck, 721 H. W. Hellman Building. Estimated cost, $25,000.

LOS ANGELES—The Los Angeles Graphite Co. will build a reduction plant for recovering graphite from Crescenta Canada tract, near here.

SACRAMENTO—The City Commissioners plan an election in April to vote on $1,883,000 bond issue, $1,200,000 of which will be used for the construction of a filtration plant. Thomas Coulter, commissioner of public works.

SAN FRANCISCO—The General Bond & Share Co., recently organized with a capital of $10,000,000, will develop a 1200-acre lease of potash properties in the Searles Lake district. Plans include the construction of a large refinery. B. Schlesinger, First National Bank Building, secretary.

SAWTELLE—The Board of Public Works, Los Angeles, will install a modern septic sewerage plant to handle the sewage here. W. T. Knowlton, engineer.

Colorado

PUEBLO—The Midwest Refining Co., First National Bank Building, Denver, will build an oil refinery here.

Connecticut

BRIDGEPORT—Charles C. Fisher, Asylum St., will rebuild and equip the garbage disposal plant recently destroyed by fire, entailing a loss of $25,000.

Florida

KEY WEST—The Bureau of Yards & Docks, Navy Department, Washington, D. C., received only one bid for the construction of a photo-laboratory here—from Ward & Pride, 307 Bisbee Building, Jacksonville, $6,792. Noted Dec. 30.

Idaho

MULLAN—The Copper King Mining & Smelting Co. plans new development work at its local properties, to include the construction of a 50-ton mill. Estimated cost, $25,000.

WALLACE—The Nabob Consolidated Mining Co. will build a concentrator having a capacity of 150 tons.

Iowa

MASON CITY—The city will build an experimental plant for the purpose of extracting the grease at the disposal plant, M. Conklin, chemist.

Kansas

PARSONS—The Missouri, Kansas & Texas R.R. will install a filtration plant at its yards near here. J. J. Johntz, engineer, has completed plans for the work.

Kentucky

PADUCAH—The Diamond Fluorspar Co., 129 South 4th St., recently incorporated with a capital of $99,000, will develop, 119 acres of fluorspar properties in this section to have an initial capacity of about five tons daily; equipment and machinery will be installed shortly. C. L. Van Meter, manager.

Maryland

CRISFIELD—The borough will build a sewage disposal plant and sewer. Estimated cost, $100,000. Norton, Bird & Whitman, Munsey Building, Baltimore, engineers.

SECURITY—The Security Cement & Lime Co., 125 West Washington St., will build a one-story, 50 x 50 ft. cement and lime plant. Total estimated cost, $20,000.

Michigan

DETROIT—Frederick Stearns & Co., Jefferson Ave., has had plans prepared for the construction of an eight-story, 100 x 110 ft. drug manufacturing plant, at Jefferson Ave. and Bellevue St. Albert Kahn, Marquette Building, architect. Noted Dec. 30.

WYANDOTTE—The city will soon award the contract for the construction of a filtration plant, having a capacity of 4,000,000 gallons. Estimated cost, $175,000. W. C. Lambert, mayor. Noted Aug. 15.

Minnesota

FAIRMONT—The city will receive bids in February or March for the construction of a 1,000,000 gallon water purification plant. E. L. Lewis, city clerk.

KEEWATIN—The village will build a sewage disposal plant. John Wilson, 300 First National Bank Building, Duluth, civil engineer, interested.

MINNEAPOLIS—The city will build a water-softening plant near the filtration plant. Estimated cost, $300,000. F. W. Cappelen, city engineer.

Montana

SALTESE—The Tarbox Mining Co. will build a concentrating mill. William Wallace, superintendent.

Nebraska

LAKESIDE—The Omaha Potash & Refining Co. will build a potash plant about twenty miles south of Lakeside. Estimated cost, $500,000.

New Jersey

JERSEY CITY—The Vulcan Iron Works, Morris St., has had plans prepared for the construction of a one-story addition to its plant on Essex St. Estimated cost, $8000.

New Mexico

CARRIZOZA—The Vera Cruz Leasing Co. will enlarge its existing mill to a 100-ton capacity and build a cyanide plant. R. B. Foster, president and manager.

Nevada

BATTLE MOUNTAIN—M. D. Farretta, Frank Childress and associates will place in operation a new 12-retort furnace for the reduction of cinnabar at their properties near here. John Ross, superintendent.

SEARCHLIGHT—The Big Casino Leasing Co. will build the first unit of its proposed plant; equipment, including two Deister-Overstrom roughing tables, a Herman ball mill flotation equipment and auxiliary apparatus, will be installed. F. E. Sharp, manager.

North Carolina

STANTONBURG—E. S. Darden and associates will establish an oil mill. Estimated cost, between $75,000 and $100,000.

Ohio

BELLAIRE—The Public Service Department has been authorized by the City Council to purchase one liquid chlorine machine for the filtration of the city waterworks. Estimated cost, $1000.

CLEVELAND—The Ohio Metal Briquetting Co., 909 Schofield Building, has awarded the contract for the construction of a one-story, 52 x 177 ft. factory at 401 Literary Rd., to Crowell-Lundoff-Little Co., 5116 Euclid Ave. Estimated cost, $30,000. Noted Nov. 15.

GENEVA—The city will build a sedimentation tank and filter bed for the waterworks plant. Estimated cost, $6000. W. C. Goddard, city engineer.

Pennsylvania

MEADVILLE—The city will build a sewage disposal plant, on the George Bosler farm.

South Dakota

DEADWOOD—The Standard Oil Co. will enlarge its plant here in the spring.

Tennessee

COPPERHILL—The Tennessee Copper Co., 61 Broadway, New York City, will build a milling and flotation plant, having a capacity of 1000 tons daily; plans include the construction of a granulating plant. Arthur L. Tuttle, general manager.

Texas

ARANSAS PASS—E. C. Ryan, Aransas Pass, has announced that New York and Boston capitalists will finance the construction of an oil refinery to have a capacity of 30,000 barrels per day at Harbor Island. The project will include the construction of a pipe line from Ranger, docks and coal and oil storage facilities. Cost will run to $15,000,000.

Virginia

HAMPTON—The Bureau of Yards & Docks, Navy Department, Washington, D. C., received only one bid for the construction of an oil storage and reclaiming building and a photographic laboratory at the Naval Air Station here—from R. R. Richardson & Co., Bank of Commerce Building, Norfolk, $28,445.

NORFOLK—The Norfolk Glass Manufacturing Co., 564 Church St., will soon award the contract for the construction of a one and two-story plant near Berkely St. Estimated cost, $200,000. Noted Dec. 30.

Washington

NEWPORT—The Bead Lake Copper Co. plans to build a new 100-ton concentrator at its properties on the Pend Orielle River.

Wisconsin

EAU CLAIRE—The Dells Paper & Pulp Co. has awarded the contract for the construction of a two-story paper mill to A. Larson & Co., 414 Main St.

HARTFORD—The International Steel Products Co., 1154 3rd St., Milwaukee, plans to build an addition to its factory in the spring. Estimated cost, $30,000. O. C. Unke, general manager.

MILWAUKEE—The Perfection Metal Co., organized by George E. Meredith and others with a capital of $99,000, will build a plant for the manufacturing and refining of metals.

MILWAUKEE—The Presto-O-Lite Co., 30 East 42nd St., New York City, N. Y., is receiving bids for the construction of a 1-story, 60 x 100 ft. compressor house for its branch filling station and service plant at 619 Trowbridge Ave. here.

British Columbia

ALERT BAY—The Beaver Cove Lumber & Pulp Co., Vancouver, will build a pulp and lumber mill. Estimated cost, $750,000.

LAKE BUNTZEN—The American Nitrogen Products Co., 905 Securities Building, Seattle, Wash., will build a chemical plant here. Estimated cost, $300,000.

SKIDEGATE—The South Eastern Mines will build a cyanide mill on gold property on Queen Charlotte Island which is being developed. A. S. Holmes, manager.

VANCOUVER—The Morrison Steel & Wire Co., Hawkes St., will rebuild its plant, which was recently destroyed by fire, entailing a loss of $100,000.

Ontario

COBALT—The Wright-Hargreaves Gold Mines, Ltd., will build a new mill and is in the market for machinery for same.

ELORA—The Elora White Lime Co. will build a new crusher plant and install machinery in same. Estimated cost, $60,000.

HAMILTON—The Steel Co. of Canada will build a benzol plant in connection with its coke ovens.

OTTAWA—The Honorary Advisory Council for Scientific and Industrial Research submitted report to Government recommending the construction of a four-story laboratory building to serve as a Central Research Institute. Estimated cost, $500,000.

SANDWICH—The Dominion Forge & Stamping Co. will build a new plant and install machinery in same. Estimated cost, $150,000. W. Herdegen, manager.

Quebec

CHICOUTIMI—Price Bros. & Co., 56 St. Peter St., will build a pulp mill. Estimated cost, $1,000,000. Sir William Price, 145 Grand Allee, president.

MONTREAL—The Pyrene Manufacturing Co. of Canada, Ltd., 3 St. Nicholas St., will build a factory. Estimated cost, $25,000.

TEMISKAMING—The Kippewa Fibre Co. has awarded the contract for the construction of twenty one-story, concrete buildings to be used as sulphite paper mills, to George A. Fuller Co., 45 St. Alexander St., Montreal. Estimated cost, $3,000,000.

THREE RIVERS—The St. Maurice Lumber Co., 2 Notre Dame St., will build a pulp and paper plant. Estimated cost, $500,000. R. F. Grant, manager.

Saskatchewan

HATTON—The Manitoba Jypsum Co., 504 Trust & Loan Building, Winnipeg, Man., will build a chemical plant here. Estimated cost, $40,000. William Main, president.

Industrial Notes

THE AMERICAN TRANSFORMER CO., Newark, N. J., has moved into an enlarged factory at 178-182 Emmet St., which is just a few blocks from its former location.

THE BROWN HOISTING MACHINERY CO., Cleveland, O., announces the following changes in its organization: Mr. Harvey H. Brown, chairman of the board of directors; Mr. Alexander C. Brown, president; Mr. Melvin Pattison, vice-president, general manager and director; Mr. Robert G. Clapp and Mr. John F. Price, directors, and Mr. Ewen C. Pierce, general manager of sales.

THE PERSOL CHEMICAL CORP., Buffalo, N. Y., has created and is marketing sodium hydroxide and potassium hydroxide in tablet form. These tablets are made up in the U. S. P. grade purified by alcohol and also in the C. P. grade made up in one and two grams and packed in one, two and five pound bottles.

THE NASSAU VALVE & PUMP CORP., Rockville Center, L. I., has moved into new and more commodious quarters in Rockville Center, where its facilities for quantity production of acid resisting valves and pumps of solid antimonial lead are materially increased. The more expeditious routing of production afforded by the better plant layout and an increase in machine space and machinery, as well as increased foundry facilities, and the addition to plant personnel of a number of experienced mechanics besides those already employed make this company fully prepared to handle the after-the-war business of equipping fertilizer, smelting, refining, dye and chemical companies with acid resisting valves and pumps.

THE LUDLUM STEEL COMPANY, Watervliet, N. Y., announces the following equipment now installed, either ready for operation or nearing completion: One 12,000-lb. steam hammer with 72-inch stroke, necessary crane and gantry rigging; one vertical water tube steam boiler working off of waste gases from the heating furnaces; two new heating furnaces to be used in conjunction with this new hammer; electric motor drive with Falk gear for the 10-in. mill, replacing one 800-hp. steam engine. The steam boilers used for this steam engine will be coupled up to existing steam hammer capacity and three additional 1000-lb. and 1500-lb. steam hammers. New grinding room has just been completed and 24 grinders installed, with another 12, making 36 in all, nearing completion. This grinding room will be used exclusively for grinding high speed steel billets. This grinding room will be fitted up with runways and other labor-saving appliances for quick handling of heavy material. Two additional 6-ton furnaces are nearing completion with an additional 10-ton crane. The new furnaces will be the Ludlum Electric Furnace Co.'s product. The total installation of electric furnaces at the Ludlum Steel Co. is now three 10-ton furnaces, three 5-ton furnaces and two 6-ton furnaces which have been made by the Ludlum Electric Furnace Corporation. A new annealing shop has just been completed containing six 15-ton annealing furnaces, and preparations are being made for the installing of two more of the same type of oil-burning furnaces.

THE NITRO PRODUCTS CO., Saginaw, Mich., is manufacturing naphthaline intermediates, specializing at the moment upon H-acid, for which they have equipment about completed to turn out regular and substantial quantities daily.

RICHARD K. MEADE & CO., Baltimore, Md., has moved its offices and laboratory from the Law Building to 11-13 E. Fayette Street.

THE ELECTRIC STEEL CO. of Indiana, Indianapolis, Ind., has been purchased by J. Rogers Halcomb and Roger B. Farquhar, Jr., formerly with the Midvale Steel Co. They will continue the business under the same name.

THE PHILADELPHIA ROLL & MACHINE Co., Philadelphia, Pa., has placed in operation a 25-ton acid open-hearth furnace. This company has also built a large pit annealing oven and a large core drying oven and is equipping the open-hearth building particularly for the manufacture of steel and steel alloy rolls.

THE SHARON STEEL HOOP Co. has started recently the No. 5 and No. 6 open-hearth furnaces in the battery at Lowellville, Mahoning County, Ohio. With the addition of these furnaces the monthly capacity of steel produced will be about 22,000 tons.

THE WESTERN RESEARCH CORP., 514-516 Eighteenth Street, Denver, Colo., has been organized by Carper, Ross & Co. and Mr. James M. McClave to handle the growing demand for industrial research and investigation. The business formerly conducted by Mr. McClave has been acquired by the new corporation and is to be greatly enlarged. A reasearch laboratory is fully equipped to solve all problems in handling minerals, non-minerals, oil, etc., and develop efficient scientific methods of treatment, furnish reports on engineering, mining, metallurgical and chemical design and construction of mills and treatment plants, also development and financing of properties which have been investigated and approved.

THE BOOTH-HALL COMPANY, manufacturer of electric furnaces, Chicago, Ill., has placed in successful operation during the past few months the following steel melting furnaces: West Michigan Steel Foundry Co., Muskegon, Mich.: 3-ton basic-castings for naval gun carriages; Monroe Steel Castings Co., Monroe, Mich.: 1½-ton-acid-steel castings; Queen City Foundry Co., Denver, Colo.: ¾-ton-basic-steel castings for Emergency Fleet Corp.; New England Steel Castings Co., East Longmeadow, Mass.: 1½-ton-acid-steel castings. In addition to these furnaces, there is also a ¾-ton acid lined furnace in operation at the plant of the Duriron Castings Co., Dayton, Ohio, used for experimental work in the manufacture of duriron, and a 1½-ton furnace at the Avery plant, Peoria, Ill., basic, used for the manufacture of tractor castings.

THE WILPUTTE COKE OVEN CORPORATION, New York, N. Y., announces that the new by-product coke oven plant of the Steel Co. of Canada, at Hamilton, Ont., will soon be in full operation. The plant consists of eighty 13-ton Wilputte regenerative by-product coke ovens, arranged in two batteries of forty ovens each. The contract date of completion called for the first battery to be put in operation on Nov. 15, and in spite of all difficulties, due to abnormal conditions, the first battery was charged on the date stipulated in the contract. The installation is complete, including by-product plant, coal and coke handling, boiler plant, etc., and will have a capacity of approximately 500,000 tons of coal per annum. The plant was designed and constructed by the Wilputte Coke Oven Corporation, New York.

THE ELECTRIC FURNACE COMPANY, Alliance, Ohio, has closed a contract with the Braeburn Steel Co., Braeburn, Pa., for a large continuous recuperative annealing furnace, for the annealing of alloy steel bars and wire. This furnace will have a capacity for annealing 75 tons per day, and an electrical capacity of 600 kw. One of the special features is that the material is heated and cooled slowly and owing to the fact that it is a special alloy steel must be soaked for a considerable time at a maximum temperature without scaling and without the use of the usual annealing box covers.

THE VANADIUM-ALLOYS STEEL CO., of Pittsburgh and Latrobe, Pa., manufacturers of high speed and alloy tool steels, have leased the offices and warerooms at 566-568 West Randolph Street, Chicago, Ill. This company will carry in Chicago a large stock of "red cut superior" high speed steel in all the standard sizes and shapes of bar stock, also treated bits for tool holders. Owing to the size of its new warerooms this company will now carry a much larger stock than formerly with which to serve Chicago and contiguous territory.

THE WELLMAN-SEAVER-MORGAN COMPANY of Cleveland, Ohio, has opened a San Francisco office at 415-417 Rialto Building, in charge of Norman S. Ross. Business originating from California, Nevada west of the 115th meridian, Lower California and the counties of Josephine, Jackson and Klamath in Oregon will receive the prompt attention of Mr. Ross.

MARDEN, ORTH & HASTINGS CORPORATION opened a new office in the Syndicate Trust Building, St. Louis, on Jan. 2, which is the eleventh branch of this corporation. The company's head office is at 136 Liberty Street, New York City. Mr. Lewis, who was formerly connected with the Chicago branch of the corporation, will have charge of the sales of chemicals, oils, dyestuffs and intermediates and tanning materials. The edible oil departments will be in charge of Mr. Schnabel, who was formerly in charge of the same departments at the Louisville branch. The St. Louis office has been opened for the greater convenience of the many customers of the corporation in Missouri and adjoining states, who will receive prompter attention by directing all inquiries to the new office.

THE INTERNATIONAL OXYGEN CO. announces the removal of its general offices from 115 Broadway, New York, to the company's Waverly works at 796 Frelinghuysen Ave., Newark, New Jersey. This centralization of the executive, sales and production departments at one point is made in order better to serve the interests of the company's trade.

What of Industrial Opportunities in France?

LIVE American manufacturers are speculating on the prospect of selling equipment and apparatus for reconstruction of industrial communities in Belgium and France. Naturally there is more or less groping about in darkness, but that condition is not confined to our manufacturers—even the French have not formulated their plans and they are in some confusion as to where to begin. The task is stupendous.

A few fundamental observations may be helpful. In the first place the devastated areas of France and Belgium must be reconstituted, beginning with that unit of society, the family. Scattered members of families must be brought together. Whether these families will then return to their former homes depends on whether the cities shall be rebuilt, and this in turn may hinge on the extent to which the industries once existing there have been re-established elsewhere. This may mean that existing communities will assume greater importance than some of those already destroyed. In any event the first problem is one of housing and food for the war-stricken people.

One obstacle to discovering what France needs is that no survey has been made to strike a balance between what has been destroyed and what has been replaced. The former is known quite well—the latter almost not at all. It seems as though our Department of Commerce should make or assist in making such a survey in the interest of our manufacturers. A difficulty is the scarcity of competent men. Another plan would be for associations of manufacturers to make their own surveys, sharing the expense. Individual concerns, of course, can cultivate the ground in their own private interest.

Something of that sort is necessary as a preliminary. France has not been conspicuous as an industrial nation, and there is no reason to assume that she will be. Perhaps the American manufacturer has little to look for in the way of European business and should turn his attention to South America. Certainly at present he should go slowly and investigate carefully. Some good advice is to be found in *Commerce Reports* for January 6 and 15, 1919, and August 27, 1918, which we commend to our readers.

Scrapping War Chemicals

EVERY once in a while we read that 280 carloads of TNT or hundreds of tons of mustard gas or an illimitable amount of phosgene or an infinity of chlorine has been dumped into the sea or is about to be cast into it. We have no actual confirmation of these harbingers

of destruction as final orders, but their persistence indicates that in the minds of too many unchemical Colonels and mystical Majors the idea prevails that chemical munitions should be destroyed because they were designed for a purpose which has ceased to exist. In this connection we do not refer to any unavoidable hazards to life, health or limb. Of course, these should be removed without cheese-paring in regard to the costs. What we object to is the sudden cessation of research, as though, now that the war is over, we do not need chemists or chemistry any more; or as though the job, being, as we hope, finished, everything should be scrapped or destroyed. This offends our business sense.

Our British cousins are keeping not only their scientific men but also those of signal ability in the administration of affairs at their posts, to aid in reconstruction. Our own Government, on the other hand, is letting too many of its valuable corps return to scholastic and industrial life.

If the rumors are true, it would be just as reasonable to throw the steel and other metals designed for use in shells into Chesapeake Bay because they will not be needed for war purposes. It has taken vast wealth and labor to prepare the store of war gases, and if the Ordnance Department does not know what to do with them, we suggest that the very able chemical staff which has accomplished so much in devising methods to prepare them be called upon to find new uses in the arts of peace. If, however, the War Department cannot bring itself to maintain its chemical service, there is the Bureau of Mines, which is a permanent institution. Although it is under the control of the Department of the Interior, Secretary LANE is not a man to be worried by red tape. Director MANNING has wisdom and understanding and we should cease to be anxious if the disposal of these things were placed in his hands. The chemical staff of the Bureau under Dr. PARSONS is not only exceedingly able and efficient but also thoroughly well administered. It has the facilities for research, and we hold that research is sorely needed.

Property should not be destroyed because it is a drug on the market. That is always bad policy. True, the substances are poisonous, but so is sulphuric acid and so is nitric acid; yet neither of these is thrown away when the market grows dull. The alkali cyanides have a well-established reputation for being poisonous, but that does not prevent them from being used in the recovery of gold. It is not good practice to run sodium cyanide down the drain, for prudential as well as for economic reasons.

Chlorine is indeed a problem, and new uses are needed in connection with the electrolytic soda industry. Nevertheless we shall not grow wise by dumping it. Its use is a problem in research which may find its solution in sewage disposal, or in any one of a considerable number of applications in industry or sanitation. Why not get busy in the Government research laboratories before the stuff is thrown away and the plants are dismantled? It is quite possible that within a year's time we shall be demanding chlorine with all our might and main.

We understand that Colonel WALKER has found an excellent market for phosgene, aside from its use as a solvent for ferric oxide to bleach sand for the glass industry. Shall it nevertheless be destroyed because it was made with intent to kill? It looks as though there were some uncontrolled legal talent at work in the Ordnance Department, which, coupling the intent with the substance, concludes that, the purpose being *non est*, the substance also should be made *non est*. We suggest that the authorities make Colonel WALKER a General, so that he may speak with the voice of authority before the remaining official pundits give military expression to their opinions.

Teach Engineering Students How to Study—First

STARTING from the oft-expressed idea "Engineers are needed as never before," many ill-considered schemes are being proposed and in some cases instituted to increase the output of our technical schools. Reduce the content of courses, graduate the men in three or even two years, or get a greater number of matriculants, is the net effect of most of the proposals. It is common knowledge that an unduly large percentage of the present graduates cannot be called engineers, in the true meaning. Yet the thought which doubtless has been given toward increasing the supply of real engineers by decreasing this proportion has so far brought few tangible results.

The boys presenting themselves for college entrance are largely volunteers. As human material they would delight a leader's eye. Properly handled they should successfully attack extraordinary difficulties. Yet an unconscionable number fall by the way, far short of the desired goal, their failure in good measure being due to improper preparation.

The average high school graduate is notoriously a "lame duck." Some of them are lacking in the mental and moral stamina necessary to attack and solve problems honestly. The high school shrugs its shoulders and blames this on home environment and pre-school training. Few indeed there are who can express themselves in correct English, or who can use applied arithmetic with a fair degree of success. But the high school blames these shortcomings on the grammar school. Who, then, is to blame for the fact that the pupils slip through the "cultural" and "humanistic" studies of the high school curriculum and at the end do not know really how to study, much less how to think?

But technical schools are confronted with a condition, and while it may do some good to point out on whom the blame should rest, their immediate problem is to turn their volunteers into engineers. Here are boys applying for a job on a four-year contract. Their chief work will be to think and study; to study hard and honestly, to rearrange thoughtfully their accumulated store of elementary facts in the proper phalanx to attack more complex problems. Yet they do not know how to study and to think, and, unbelievable as it may seem, no one makes an effort to teach them these fundamentals. Naturally, they continue with boyish abandon their carefree attendance to forms, such as going to lectures and carrying books to their rooms; but at other times they link arms with a happy chum and joyously trust to the lucky star which has brought them thus far. Sooner or later they discover the startling revelation that life is not child's play and they have indeed wasted golden hours.

One might profitably draw an analogy from like problems arising in intensified shop production. Machines could be bought but no men found to operate them; to put an unskilled man at them would certainly ruin the material, probably damage the machine, and very possibly injure the workman. Yet under the care of a competent instructor, an intelligent person could be turned into a successful operator in a very few weeks. Intensified individual instruction in elementary details solved the problem of skilled labor shortage.

If the technical schools would first teach their freshmen how to study and how to think, they would recover the time spent tenfold in later courses. Turning unskilled boys loose in college has resulted in a compromise of academic ideals, damage to the reputation of higher education and in many cases ruin of the boy's future expectations. More engineers of a sort may be had by shorter courses, fewer vacations and examinations, but more engineers of sorts may be had by preliminary and intensive training in the fundamental work of studying and thinking.

The Iron Map of Europe

PIG iron and steel do not grow, they are made—a fact that seems to be overlooked by those who have already sketched the iron map of Europe that is to obtain in future. Apparently they assume that the restoration of "German Lorraine" to France means that a quantity of pig iron and steel production corresponding to the 21,100,000 tons of iron ore produced by the territory in both 1912 and 1913 will be subtracted from the German production and added to the French production. It does not follow that because the territory becomes French again there will be an increase in French production of pig iron equal to the tonnage of iron ore formerly produced in it, and an increase in French steel production corresponding with such increased quantity of pig iron. These commodities must be made, they do not grow. The iron ore will probably be mined as formerly, but it remains to be determined who will smelt it into pig iron and who will convert the pig iron into steel.

The habitat of the pig iron and steel production will not be decreed by the Peace Conference, except as it may establish certain principles and rules, dictated by taking cognizance of economic, financial, metallurgical and engineering considerations.

Before the war there was a very complicated movement of the Lorraine or "minette" ores. The ores were produced in French Lorraine, German Lorraine and Luxemburg, and were consumed by these three countries plus Belgium. Some of the ores have an excess of lime, some of silica, and thus a certain amount of interchange over international borders was dictated by metallurgical considerations, while Belgium had to be supplied *in toto*.

France, however, while importing only 500,000 tons of ore from German Lorraine, exported to Germany more than 2,000,000 tons, of which half was consumed in Westphalia and the other half in German Lorraine and the Saar district, being attracted thither in limited quantities by the fuel. For a time during the peace negotiations, by the way, a contingent of the French set up a claim for the Saar coal basin, as requisite for the working of the ore, but this claim has been abandoned. Westphalia also consumed nearly 3,000,000 tons of ore mined in German Lorraine, and some of the pig iron produced by the Germans in Lorraine went to other districts of Germany for conversion into steel, while in general there was a flow of steel to more interior points for further working.

One does not know what individuals will own the ore mines, blast furnaces and steel works now in the territory that is to be transferred from the German to the French flag, but there is one thing that every one ought to know, that all Europe has got to work hard for years, and hence that all work that is done must be along the best engineering and metallurgical lines. If iron ore, or pig iron, or unfinished steel, or finished rolled steel needs to cross the new international boundary in order to accomplish the best economic results, that movement will have to occur.

In 1913 France produced 4,686,866 metric tons of steel ingots and Germany 18,958,819 metric tons of steel ingots and castings, both outputs being new high records. It is a simple matter to assume that the restoration to France of the aggrandized portion of Lorraine will add a certain tonnage to the French figure and subtract from the German. The arithmetical computation has indeed been made, and noting that the British capacity, with the completion of some work now under way, will be 11,000,000 or posibly 12,000,000 tons, the observation has been made that the three countries will be almost evenly balanced in steel production.

The French have a great deal of work ahead of them and they are very short of man power, while their financial resources are limited. No country has exercised more care to conserve its credit than has France, but that probably means conservatism for the future. The French will be well content if they can find full employment for their man, and woman, power and their capital. They will not set any certain mark, of 5,000,000, or 7,500,000, or 10,000,000 tons of steel production to be accomplished, but will endeavor simply to employ all their resources to the best advantage. In French Lorraine the blast furnaces and steel works have been destroyed or greatly injured, while the iron ore mines are reported practically intact. Restoration is needed, and this may possibly take more than a year. Some new steel works have been built during the war, and undoubtedly these will continue in operation.

It is easy to say that France will have such and such a steel capacity after the adjustments are made and assume that production will be in accordance. It would be still easier to say that the capacity of the United States is 50,000,000 tons, and accordingly assume that the United States will produce 50,000,000 tons each year, but the difficulty there would be that we are not doing it, and are in no way to do it in the near future. The fact that France is far away does not justify our taking liberties. The thing will have to be worked out, and iron ore mined in France, in reunited Lorraine, will probably pass to Germany, probably also some pig iron and perhaps partly finished steel, just as large tonnages of ore will continue to move into Luxemburg and Belgium.

New Jersey Chemical Society

THE third regular meeting of the New Jersey Chemical Society was held in the Wistaria Room at Stetter's in Newark Monday evening, Jan. 13. The evening opened with a banquet attended by 100 members, which was followed by the first "Rubber Night," with an attendance of more than 200 members and guests. Following the plan adopted by Dr. Calvert of the program committee, there was a scientific paper, read by Mr. George D. Kratz of the Falls Rubber Co., Cuyahoga Falls, Ohio, on "The Effect of Certain Accelerators on the Vulcanization of Rubber," which we expect to publish in a later issue. The popular paper of the meeting was read by Dr. Frederic Dannerth of Newark and was entitled: "Some American Substitutes for Rubber, From the Viewpoint of the Investor and the General Consumer."

Dr. Dannerth differentiated between artificial rubber, imitation rubber, synthetic rubber and rubber substitutes. In fact, some importers, he said, were inclined to import resinous gums under the tariff paragraph of "india rubber, free." The question of rubber substitutes, he continued, is of great importance because it involves our national welfare, and because the finest grades and most valuable varieties of rubber grow entirely outside the mainland of the United States. It is therefore most necessary and desirable to make an industrial survey of American raw materials and products which come into consideration.

The speaker enumerated 17 groups of materials, including raw oils; fats and waxes of vegetable and animal origin; sulpho-chlorinated oil products, called white substitute; sulphurized oil products, generally known as black substitute; sulphonated oil products of the type of turkey red oil; pitches and solid hydrocarbons obtained from petroleum, coal tar, asphaltum and fatty acid distillation; synthetic resins of the condensite type; natural resins obtained from spruce in the Carolinas, guayule in Mexico and chicle in Central America; carbohydrates, including starch and sugar; water-insoluble soaps prepared from lead, magnesium, aluminium, zinc and calcium; animal proteins such as glue and casein of cow's milk; and, finally, gums related to rubber. These include guayule obtained in Mexico from the parthenium shrub and chicle obtained in Yucatan from the achras tree.

Dr. Dannerth emphasized the fact that rubber and cotton are today "key materials" for the rubber goods industry, and no pneumatic automobile tires are made without rubber and cotton. Long staple cottons are being cultivated today in Arizona and the Imperial Valley, but high-tensile rubber is entirely absent as a natural resource. Virtually all plantation rubber is brought from the East Indies, a distance of 8000 miles, or from Brazil, a distance of 3000 miles. The per capita annual consumption of rubber goods in the United States is about ten pounds, which means that each person uses or obtains the benefits of ten pounds of all kinds of manufactured rubber goods each year.

"Will the rubber plantation owners repeat the $3 rubber market performance of April, 1910?" This was the question brought up for consideration by the speaker, in view of the approaching declaration of peace. The speaker also called attention to the statement made by one of the large plantation owners in the New York Rubber Conference in 1912 to the effect that he could, if need be, deliver rubber in New York City at a price close to 25 cents per pound. The London *Times* was recently quoted as saying that 80 per cent of the plantation rubber acreage is now under British control. But, Dr. Dannerth said, this should only serve to show that the British recognize the importance of controlling "key materials."

It was stated that the consumption of rubber in the United States in 1917 was 330,653,600 lb. of raw rubber and our annual imports of guayule rubber from Mexico are about 5,100,000 lb. Synthetic or factory-made rubber is a reality, but the cost of manufacture has not been cut down low enough for use during times of peace. This is the only material which possesses the peculiar properties of natural rubber, namely, the ability to gain in tensile strength and elasticity to an enormous degree by the process of vulcanization. But the substitutes for rubber possess many properties which rubber does not possess.

Annual Meeting of the Chemical Alliance

The second annual meeting of the Chemical Alliance was held in New York Jan. 23 to 25, at which time the question of the future of the organization was considered. Superseding the advisory committee on chemicals of the Council of National Defense, the principal function of the Chemical Alliance was that of a war agency to assist the Government. The need of an organization representative of American chemical industry is quite as great now and in the future as it has been in the past. Three important problems must be solved. The first relates to the urgent need for the validation of war contracts which involved vast expenditures on the part of the industry, but which, under stress of war, were not legally executed. Fresh legislation should be enacted speedily to enable the Government to take care of its moral obligations. The second matter demanding consideration is the re-sale of material bought by the Government under war contracts and to be resold as soon as practicable. The third question refers to the possibility of expanding foreign trade in chemical products. The directors announced that they would support the continuance of this organization in its present form and when the matter was put to a vote at the general meeting, there was unanimous concurrence. A special committee appointed to study foreign trade is expected to report its findings within two months.

Importation Restrictions Removed by War Trade Board

The War Trade Board announces that previous restrictions upon importation of chromite, monazite sand, manganese ore, copper ores, copper concentrates, pyrites, graphite or plumbago and graphite crucibles have been removed and that licenses will be issued for the importation of these materials from any country. It is further announced that with the exception of pig tin, tin ore and concentrates, the supervision heretofore exercised by the War Trade Board through various associations in the several trades over the distribution of raw materials in this country has been removed.

Sale of Surplus Materials and Scrap by the Ordnance Department

ALL surplus, unused or obsolete construction and manufacturing materials, semi-finished and completed parts, miscellaneous supplies, etc., left over at time of cancellation or termination of Ordnance contracts, or surplus at arsenals and supply depots will be ordered sold or stored as conditions require by the subcommittee on sale of material of the Salvage Board. The actual sale of this material will be handled by the material branch of the stores and scrap section of the Ordnance Department through the district stores and scrap managers, located in each district Ordnance office.

Capt. Ralph C. Shaw, chief, material branch, located in Group B, Section 1, Room 303 of the Ordnance building, at Seventh and B Streets, Washington, D. C., is compiling lists of the materials to be disposed of as promptly as these materials are reported for sale. Likewise he is compiling lists of buyers of given classifications of materials. This information is being imparted to the district managers. Any Government agencies or others interested in the purchase of any materials having been or to be ordered sold by the Salvage Board should communicate with the material branch.

All scrap left over from the operation of Ordnance contracts will be sold by the scrap branch of the stores and scrap section, operating through the stores and scrap managers of the district Ordnance offices. This scrap consists of different kinds of steel in sheets, billets and turnings, scrap steel parts, cupro-nickel scrap, antimonial, lead dross, silk and cotton waste, burlap, spent acids, etc.

District representatives of the stores and scrap section can give information as to scrap available. Likewise Lieut. Schleck, chief, scrap branch, Group B, Section 1, Room 305, will be glad to advise as to amount of scrap on hand at any point, price at which it is being held, etc. He will also be glad to receive names of Government agencies or other possible buyers of these materials.

Plans for close co-operation between the Government and industry in the sale of surplus Government supplies are also being worked out by the director of sales of the War Department and the War Service Executive Committee of American Industries. The policy of the Government with respect to the sale of supplies, as outlined by C. W. Hare, director of sales, will be to consult representatives of the industries concerned whenever sales are to be made in volume likely to disturb trade conditions.

The War Service Executive Committee consists of the members of the executive committee of the Chamber of Commerce of the United States, with the addition of others to make it more completely representative of all the groups of American industry.

Little Platinum in Black Sands

THE Bureau of Mines recently investigated the black sands of the Pacific Coast to ascertain whether there was a possibility of obtaining platinum therefrom. The results of the investigation may be summarized by the statement that in general the black sand deposits are disappointing in both value and quantity; they rarely contain enough gold and platinum or occur in adequate quantity to be exploited at a profit. There are, it is true, a few favored places where small areas of the black sand show some precious-metal content, and these may become the site of small operations. The deposits in many places contain appreciable amounts of magnetite, chromite and ilmenite, but these minerals are generally too scattered and too poor to constitute an important source of iron ore, especially in competition with the known deposits of magnetite on the Pacific Coast.

The chief difficulties in the profitable exploitation of these deposits are, first, lack of uniformity in occurrence and metallic content, and, second, the high cost of mining and treating the materials.

Black-sand mining in the past has offered a fruitful field for unscrupulous promoters and has been especially alluring to men having little knowledge of mining or mining methods. These swindlers usually claim to have some wonderful machine or process for extracting gold and platinum from the sands. Many of these agents made the most extravagant claims for the processes or machines. Some of these process men were so bold as to claim that they could recover gold and platinum where it could not be detected by any known scientific method. As a result the Pacific Coast is strewn with the wrecks of many kinds of experimental machines and of plants that bear evidence to the credulity and childlike simplicity of those who had been induced to invest their money in schemes for treating the sands.

Technical Paper 196, "Notes on the Black Sand Deposits of Southern Oregon and Northern California," has just been issued by the Bureau of Mines.

Copies of this report may be obtained free by addressing the Director of the Bureau of Mines, Washington, D. C.

New York Meeting of the American Institute of Mining Engineers

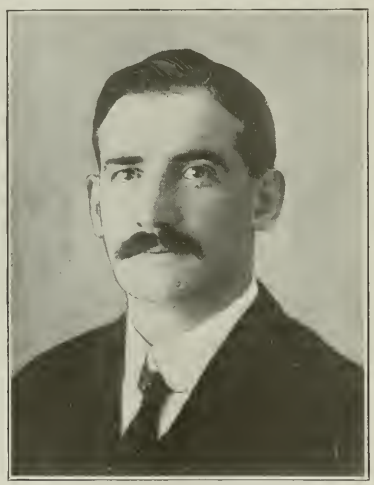
The one hundred and nineteenth meeting of the American Institute of Mining Engineers will be held at Institute headquarters, 29 West 39th Street, New York City, Feb. 17 to 20, inclusive. Technical sessions will be devoted to non-ferrous metallurgy and metallography, conducted by the Institute of Metals Division; industrial organizations; petroleum and gas; iron and steel; mining, milling and geology; coal; and electric welding, the last being considered at a joint session with the American Institute of Electrical Engineers. Tuesday, Feb. 18, has been designated as Canadian Mining Institute day, at which time there will be a discussion of international co-operation in mining in North America and uniform mining law for North America. A session of the National Research Council will be held Wednesday, Feb. 19, and on Thursday, Feb. 20, there will be an all-day excursion to the plant of the Federal Shipbuilding Co. at Newark, N. J., for the inspection of electrical welding of ships. Luncheon will be served each day at Institute headquarters. Social features of the meeting are a smoker, a travelogue by George Miller Dyott, late of the Royal Naval Air Service, and the annual banquet at the Hotel Biltmore. Special entertainment for ladies has been provided for by the Woman's Auxiliary.

Perkin Medal Presented to Frederick G. Cottrell

Award Made for the Recipient's Work in the Electrical Precipitation of Suspended Particles in Gases—Dr. Cottrell Describes Recent Work in the Commercial Production of Helium for Use in Balloons

THE thirteenth impression of the Perkin medal was presented to Dr. Frederick Gardner Cottrell, chief metallurgist of the U. S. Bureau of Mines, at a meeting of the New York Section of the Society of Chemical Industry on Friday evening, Jan. 17, at Rumford Hall. Major Charles E. Sholes, the honorary chairman, presided.

The hall was completely filled by an audience that represented a wide scope of chemical activity, both pure and applied, and messages of regret were read from the Secretary of the Interior, the Director of the Bureau of Mines, the Secretary of the Smithsonian Institution and others.



DR. FREDERICK G. COTTRELL

Joint Meetings Discontinued

Chairman Sholes announced that the joint meetings with the New York Section of the American Chemical Society, which the pressure of war-time conditions had made necessary, would be discontinued and that the meeting of the Society of Chemical Industry scheduled for April would be held as originally planned. On that occasion there will be made the first award of the Grasselli medal, founded by the corporation of that name and to be awarded each year for the best thesis which, in the opinion of the committee, suggests or records the newest or best helps or accomplishments in applied chemistry. The vice-chairman, Dr. Parker C. McIlhiney, offered a resolution of felicitation on the close of the war to be sent to the parent society, which was duly adopted.

Mr. Charles H. McDowell, the recent chief of the chemical division of the War Industries Board, spoke briefly of the satisfactory way in which the chemical industry of the country played its part in the war, and the fine spirit of co-operation shown by chemists and chemical engineers in meeting emergencies. The result was that our chemical accomplishment excelled that of many other industries.

Major Sholes' Remarks

Major Charles E. Sholes, chairman of the New York Section, in his introductory remarks said:

"Of course, it is always an honor and privilege to serve one's country anywhere. But the public seems to think that at least during this war it was not such a great honor to have served in Washington. Every man I know applied for field service abroad and was promised it and was bitterly disappointed not to get it.

"I suppose the answer is that some one had to arrange for the food, clothing, guns, powder, ships, etc., and to keep the books—and be the goat. So we have been striving to be very good goats. But it is perhaps fortunate that the men now in Washington have the saving sense of humor, else they could not have worked so hard and cheerily and proudly at their jobs. Just now they are telling a story of fifty years hence when our grandchildren are discussing the present war, and Mary says to John, 'Was your grandfather in the great war?' John says, 'Yes, he was in the Ordnance Department.' And Mary says, 'So was my grandmother!'

Pleased at the Honor

"Perhaps it is through such view of service in Washington that many of us are rather astonished and particularly pleased when any one in Washington is publicly honored—and gets away with it. So it is a great pleasure for me to ask the senior past president of the society, Dr. Chandler, to address Dr. Cottrell of the Bureau of Mines in Washington, D. C., and present the Perkin medal."

Dr. Chandler, who had previously received an ovation when he entered the hall, reviewed Dr. Cottrell's life and work, and presented the medal. His address follows:

Perkin Medal Presentation Address

By C. F. Chandler

"Mr Chairman and Brother Chemists:

"It is my privilege and very pleasant duty, as senior past president of the Society of Chemical Industry residing in this country, to present to Frederick Gardner Cottrell, B. S., A. M., Ph. D., the thirteenth impression of the Perkin medal, in recognition of his most original and valuable work in applied chemistry.

"Dr. Cottrell was born in San Francisco in 1877, where he received his early education. His degree of bachelor of science was conferred upon him by the University of California in 1896. He continued his scientific studies at the University of Leipsic, graduating in 1902 with the degree of doctor of philosophy.

"Returning at once to America, he became instructor in physical chemistry at the University of California,

later assistant professor. This position he held till 1911, when he joined the staff of the Bureau of Mines in Washington. Here he was at first the consulting chemist, then successively chief of physical chemistry, chief chemist, and finally chief metallurgist, which position he still holds.

"After graduating at the University of California, he continued his work there, devoting his attention to studies of hydriodic acid, liquid and gaseous, which enabled him to increase greatly our knowledge of the physical and chemical properties of this substance. His papers on this subject were published in the *Journal* of the American Chemical Society, 1896 and 1899, and in the *Journal of Physical Chemistry* in 1898.

"In 1900 he published a very elaborate investigation on manganous sulphate in the *Journal of Physical Chemistry.* This investigation was made with a view to throwing light upon the very interesting case of equilibrium in systems of manganous sulphate and water. His first publications while in Germany related to the genesis of some of the double and triple salts of magnesium occurring in the Stassfurth saline deposits.

"Dr. Cottrell's inaugural dissertation was entitled 'The Residual Current of Galvanic Polarization Considered as a Problem of Diffusion.' It was published in 1903. From this date on he continued to publish reviews and investigations too numerous for me to refer to here. Specially interesting are papers on liquid air plants, 1905 and 1906.

His First Fundamental Experiment

"Dr. Cottrell's most elaborate and valuable investigations relate to electrical precipitation of particles of liquids and solids and began in 1906 with his work on sulphur trioxide fumes which are not easily absorbed by water. It had long been known that electric brush discharges caused fog to clear. Sir Oliver Lodge had worked along this line. Dr. Cottrell describes his first fundamental experiment on page 5 of his paper on 'The Electrical Precipitation of Suspended Particles,' published in the *Journal of Industrial and Engineering Chemistry,* August, 1911.

"As this shows the beginning of one of the most important contributions to industrial chemistry, I feel that I can afford to consume two or three minutes of the time allotted to me to quote this experiment, from Dr. Cottrell himself:

> It may be of interest to note that the clue to the solution of this difficulty came from an almost accidental observation. Working one evening in the twilight when the efficiency of the different points could be roughly judged by the pale luminous discharge from them, it was noticed that under the particular conditions employed at the time this glow became appreciable only when the points had approached the plates almost to within the distance for disruptive discharge, while at the same time a piece of cotton-covered magnet wire which carried the current from the transformer and commutator to the discharge electrodes, although widely separated from any conductor of opposite polarity, showed a beautiful uniform purple glow along its whole length. The explanation lay in the fact that every loose fiber of the cotton insulation, although a relatively poor conductor compared to a metallic point, was still sufficiently conductive from its natural hygroscopic moisture to act as a discharge point for this high potential current, and its fineness and sharpness, of course, far exceeded that of the sharpest needle or thinnest metallic wire. Acting on this suggestion, it was found that a piece of this cotton-covered wire when used as a discharge electrode at ordinary temperature proved far more effective in precipitating the sulphuric acid mists, which were then the object of study, than any system of metallic points which it had been possible to construct. Perhaps the greatest advantage thus gained lay in the less accurate spacing demanded between the electrodes of opposite polarity in order to secure a reasonably uniform discharge.

"The first installation of his system was made at the Hercules powder plant at Pinoli, Cal., where there was a small contact sulphuric acid plant. There he used a 20,000-volt alternating current, rectified into a direct current by a motor-driven contact apparatus, and sent this current, by means of pubescent (hairy) asbestos electrodes, through the wet sulphur trioxide fumes and obtained precipitation.

Eliminating Fumes From Smelter

"This process, though successful, was not sufficiently profitable to warrant extensive use. It would probably have died had it not been that the nearby Selby smelter was in trouble. This smelter had a large plant near one of the tunnels of the Southern Pacific Railroad, and with certain winds the fumes of sulphur trioxide from the silver dissolving house would fill this tunnel with choking fumes, and finally legal proceedings were started to close the smelter plant. At this juncture Dr. Cottrell erected a small electric plant which met the difficulty completely and is running today, yielding dilute sulphuric as a by-product.

"But for the above-mentioned legal procedings the Cottrell process might never have materialized. The knowledge that fumes and smoke could be Cottrellized made the fume-pestered farmers all over the West sue the smelters right and left and satisfied the courts and juries that they were not asking the impossible of the smelters.

"The story of the Cottrell process for several years has been told in the news columns of the papers. Not alone has he taken the sting out of sulphuric acid waste fumes of smelters; he has brought down poisonous arsenic, saved metal dust otherwise going to waste, saved the orange groves from cement kiln smoke and recovered potash from that cement smoke to put on those very orange groves for fertilizer. The dust in the air, which was death to the trees through the clogging of the tender pores of their leaves, when duly Cottrellized and sacked and emptied on their roots, has given them new strength and life.

Extension of the Invention

"It would take a long time to give you a realizing idea of the marvelous extension of this Cottrellizing invention. I will content myself by giving you one example which I saw in the *Evening Post* of Jan. 11 last:

> Montana now has the tallest chimney-stack in the world, by a dozen feet, and in other dimensions it is immensely greater than its rivals. This is the recently completed stack of the Washoe reduction works of the Anaconda Copper Mining Co., which is 585 ft. 1½ in. in height. The outside diameter of the base, built in the form of a truncated octagonal pyramid, is 86 ft., and the walls are 5 ft. 4 in. thick at this point. The stack contains the equivalent of 6,672,214 common brick. Conducted through a vast flue system from the furnaces, the smoke will pass into chambers where will hang 111 miles of chains, electrified by a high-tension current. All the particles in the gases are electrified by contact as they pass through the links, and are vio-

lently repelled to be attracted by great plates between which the chains are suspended. These plates are grounded to form a negative pole. When they are thickly coated, the circulation will be diverted, the current shut off, and the accumulations will drop into hoppers.

"Dr. Cottrell's more recent work of investigation has had to do with the securing of helium gas for war balloons, which, being absolutely incombustible, is a wonderful substitute for inflammable hydrogen, while it is only slightly inferior in ascensional power. The helium is obtained from certain gas wells by liquefying out all the other constituent gases.

"I think I must cut my story short at this point and leave to Dr. Cottrell himself and Mr. Speed the pleasure of telling you of the Doctor's varied work at the Bureau of Mines and among the field experiment stations, as well as about the 'Research Corporation, an experiment in public administration of patent rights,' in which he takes such an active interest. I must say one more word: Dr. Cottrell has been granted many patents for his inventions and has generously donated them to the use of the public.

Conferring the Medal

"Frederick Gardner Cottrell, doctor of philosophy, my dear friend:

"It gives me the greatest pleasure, as the representative of the Affiliated Chemical and Electrochemical Societies of America, to place in your hands this beautiful Perkin medal, as a token of the appreciation and affection of your fellow chemists."

Cottrell's Work in Dewatering Oil

After Dr. Cottrell's speech of acceptance, printed in full elsewhere, Mr. Buckner Speed paid a tribute to Dr. Cottrell as follows:

"Dr. Cottrell has been, to those of us who have known him for the last fifteen years, a dear friend and gay companion. The fame and recognition that have come to him for the Cottrell process are less to us than the admiration we have for his unselfish character, his constant putting of his own interests entirely in the background and his remarkable imagination and his quick sympathy and helpfulness. On one occasion I remember his saying, at the completion of one of his larger pieces of work: 'Oh, I did not do much of it—I merely acted as a catalyzer to the boys who really did the work.' He has truly been a catalyzer to a host of us who have had the deep delight of working with him and coming in contact with his perennially fresh and keen imagination as well as his patience in the trying times that accompany all large efforts.

"This is the way the man's mind works: I recall some twelve years ago, when he was working on the precipitation of smelter smoke, I asked him for help on what seemed to be scarcely an allied problem—the freeing of California crude oil from its emulsified water. Instantly his mind worked with a snap: 'Why,' he said, 'it's the same problem. For air, put oil, for smoke particles, the minute water particles' and then his favorite form of expression: 'What will happen if we put a high electrostatic stress on the oil?' Then, in his characteristic quick manner, in a few minutes there were thrown together a beaker of oil, a spark coil and two pieces of copper, and lo! the de-emulsification of the California oils had been solved. Within a few minutes, on a block of paraffine under the microscope, there was spread out a drop of the emulsified oil, with two electric wires touching its edges. When the spark coil was put in operation the water drops were seen to arrange themselves in the field of the microscope like the iron filings between the poles of the magnet, to dance about and jiggle themselves into larger drops; and in these few minutes of experimentation the problem was solved by which millions of barrels of unmerchantable California oil were rendered fit both for refining and for fuel purposes.

"It was a familiar phrase to be heard in the University of California anywhere from the botany to the physiology departments when any question of any description came up: 'Oh, go over and talk to Cott about it—he doesn't know anything about the subject, but he will put some idea in your head before you have talked with him ten minutes,' and this he invariably did. This is the work he is now doing in Washington; and all over the country, wherever he touches an industry, there he leaves the germ of a thought that months later will come out as a manufacturing process. Such a man's work cannot well be measured by the achievements that have been credited to him."

Commercial Production of Helium

By Frederick G. Cottrell

MR. CHAIRMAN, Dr. Chandler, Ladies and Gentlemen: It is with a profound sense of appreciation on the one hand and of added responsibilities on the other that I accept this medal as a symbol of your approbation, friendship and confidence. I value the two former more than words can express, and this beautiful emblem will ever serve to keep clearly before me the responsibility to justify your confidence by striving to maintain unbroken the long line of high traditions of public service with which this award is associated on both sides of the ocean. I wish to thank you, Dr. Chandler, for this medal and for your kind words and, through you, the members of the awarding committee and the societies which they represent.

I am aware that it has been customary for the recipient of this honor to review the history of the subject particularly cited in the award, but the present year has witnessed the breaking of so many precedents and I have already on former occasions so thoroughly told you all that I know about electrical precipitation that tonight I shall take the liberty of dealing chiefly with quite another subject, though one which attracted my serious attention and study even earlier than electrical precipitation.

This is the industrial liquefaction and separation of the so-called permanent gases. My justification for this particular selection lies in the general interest at present in scientific problems whose solutions have been accelerated by the pressure of war needs, the case in point forming an interesting example in connection with the production of helium as a balloon gas.

Before turning to this, however, it may interest you if I briefly outline a few recent developments in administration of patents which, though not specifically referring to electrical precipitation, have to a certain degree perhaps been a by-product of the successful ad-

ministration of the precipitation patents by the Research Corporation.

Despite all the criticism which one hears of our American patent laws, I am disposed to look on them as remarkably satisfactory as far as they go and to feel that what is needed is not so much radical changes in the form and method of granting a patent as in the provisions for adequate administration, guidance and control in the interests of all concerned after it leaves the Patent Office.

Object of Research Corporation

The prime object to me in the formation of the Research Corporation was to furnish an experimental laboratory, as it were, in this most interesting branch of economics, and I have always looked upon the precipitation patents chiefly as mere kindling to start a fire under its boiler. If they have been able to generate some steam on their own account, it is of course gratifying, but that still does not distract my attention from the original aim.

The public's interest in the administration of patents has had surprisingly little attention when we compare it with other great problems of monopoly such as the railroads and the great fabric of corporate business. The patent laws as enacted in the early part of last century were entirely adequate to the simple structure of industry and economic life of the time, and it is amazing that they have functioned so well as they have through all the growing complexity ever since.

The attempt to work out in Congress sweeping reforms in the patent laws on the basis of our present knowledge would be a most difficult and even dangerous task, as well illustrated by the hearings on the Oldfields bill a few years ago. This is chiefly because we have little or no experimental data on what would happen if we tried by mandatory legislation to force at once on all patentees or their licensees and assignees new business methods which, although conceived in the most helpful spirit of fair play to all, would, when tried in practice, undoubtedly encounter innumerable unforeseen complications which might work great individual injustice besides actually hindering general industrial development. For this reason the somewhat unique sort of experimental work on patent administration purely in the public interest which the Research Corporation is doing appears highly important. Heretofore the study of patent questions has of necessity been approached almost wholly from the standpoint of one or other of the special interests concerned, such as that of the inventor, the patent bar or the large companies purchasing or operating under patents; while the broad, general interests of the whole public have not, as a rule, had the advantage of intensive continuous study and presentation by any agency wholly devoted to this purpose.

Interest in Patent Legislation

The most recent evidence of growing interest in this subject is a bill (S. 5265), introduced in the United States Senate on Jan. 2 by Senator Kirby, chairman of the Committee on Patents, which provides:

> That the Federal Trade Commission be, and hereby is, authorized and empowered to accept assignment of, or license under, to develop, to issue or refuse to issue licenses under, to encourage the industrial use and application of, and otherwise to administer, on behalf of the United States, under such regulations and in such manner as the President shall prescribe, inventions, patents, and patent rights which said commission deems it to the advantage of the public to be so accepted, as these may from time to time be tendered it by employees of the various departments or other establishments of the Government, or by other individuals or agencies; and to co-operate, as necessity may arise, with scientific or other agencies of the Government in the discharge of the duties herein set out.
>
> That the Federal Trade Commission be, and is hereby, authorized and empowered to collect fees and royalties for licensing said inventions, patents, and patent rights in such amounts and in such manner as the President shall direct, and shall deposit the same with the Treasurer of the United States; and of the total amount of such fees and royalties so deposited a certain percentum, to be determined by the President, shall be reserved, set aside, and appropriated as a special fund to be disbursed as directed by the President to remunerate inventors for such of their inventions, patents, and patent rights contemplated by this act as may prove meritorious and of public benefit.

This bill had its inception in the need felt for more adequate means of carrying the scientific developments made in the Government laboratories through to the public in their most useful and available form, and was sent as a suggestion in nearly its present form by Secretary Lane to President Wilson last August and referred by the President to the Federal Trade Commission for comment. During the war this latter body has administered enemy-owned patents in much the same manner and, therefore, already has much of the machinery and experience needed. The Commission, after careful study of the matter, reported favorably on the proposal, and one of the President's last acts before sailing for Europe was to send the bill with a strong recommendation to Chairman Smith of the Committee on Patents in the House, where hearings are soon to be held upon it. In the meantime, it has been introduced in the Senate to expedite its consideration by both houses. As the bill is attracting wide interest and no opposition seems to have developed from any quarter, its early passage is anticipated. This would be especially useful just now when the output of the Government's laboratories has been so increased by war activities and we are faced with the problem of dealing with many incidental discoveries and inventions coming therefrom, but having a predominantly peace-time significance.

What the Bill Contemplates

No matter how potentially valuable a purely scientific discovery is, it seldom benefits the public at large until it is carried through to industrial and commercial development and connected with the well-established avenues of trade. This is what the present bill is primarily intended to do. Incidentally also it automatically provides the expenses for its own administration as well as means whereby a modest pecuniary recompense may be awarded the discoverer or inventor of anything which through this channel eventually proves of material benefit to humanity. There are also signs of similar interest stirring in Canada and across the water, which it may be hoped presages a general and more active recognition of just these responsibilities on the part of government. It is, of course, particularly in the case of patents on broad fundamental projects that such an administration is of most importance to the public. The subjects both of electrical precipitation and that of liquefaction of

gases, to which we now turn, may excellently serve as suggestive examples.

The fact that my own connection with this latter work has been more from the administrative than the strictly technical or scientific side would make me hesitate to present it on the present occasion if it were not that looking back over the history of electrical precipitation a similar condition is evident, forcing me to the conclusion that even there my most useful services were in securing for the earlier fundamental suggestions of Sir Oliver Lodge and others the sympathetic consideration and practical large-scale development along lines of well-recognized engineering practice which they deserved but which had heretofore been lacking.

In 1904 it fell to my lot to set up and operate a liquid-air plant of the Hampton type at the University of California; and, in studying that installation, I became greatly impressed with the ultimate possibility of producing very cheap industrial oxygen by liquefaction and distillation of air, but was equally impressed with the very crude thermodynamics which, from a modern engineering standpoint, all the then common systems represented. Shortly thereafter I published two articles emphasizing some of these points and commenced experimental work along this line.[1] But pressure of other duties and lack of facilities prevented my carrying the latter very far. Ever since then, however, I have preached the importance of development in this field and have tried to follow up and post myself on each new attempt that came to my attention.

Quest for Cheap Oxygen

In assuming charge of the metallurgical division of the Bureau of Mines in 1916, it seemed that the quest for really cheap oxygen had become more than ever a large and legitimate part of my regular work; but, realizing my own limitations and the Bureau's inadequacy of material facilities, I strove to suggest, stimulate and collect inventions and developments rather than attempt to originate anything in this highly technical field.

In connection with the Bureau's laboratories at the International Exposition at San Francisco in 1915, we had already made a strenuous effort to interest the commercial oxygen companies in a co-operative experiment for the application of oxygen or enriched air to metallurgical furnace practice, largely in the hope of stimulating interest in the whole subject, but the project failed to receive sufficient support to be undertaken.

Oxygen as sold to-day in steel cylinders is so expensive that it usually fails to suggest even faintly the ultimate possibilities for low-cost production, in which latter case it would be of course simply piped at moderate pressure straight from the separating plant to the furnace. Thus, $200 a ton for even moderately pure oxygen is a very low price in steel cylinders to-day, whereas on the very large scale where unit cost of plant, overhead, sales expenses and the like are greatly reduced and compression into cylinders, transportation of same, etc., are completely eliminated, we come down to the power consumption for the actual separation as the largest and dominant factor of ultimate cost. Let us see what limits this sets. The individual steps in the process of liquefaction and separation of gaseous mixtures may all be made thermodynamically reversible to much the same extent in practice as are those of the steam engine and the air compressor. The chance for inventive skill lies chiefly in the selection of these individual steps from the alternatives long since clearly recognized and their combination into a consistent series. The difference in efficiency of present commercial processes resides in the acumen with which this choice and combination has been carried out and in the mechanical perfection of the apparatus in which the system is embodied.

The Problem

The final measure of theoretical efficiency is, of course, the degree to which reversibility in the thermodynamic sense has been approached. Air, for example, is only a mixture and not a chemical compound of oxygen and nitrogen and, therefore, no energy has to be supplied in its separation to overcome chemical affinity, but we do have to overcome what we may call the force of diffusion of the two gases in effecting their separation. In other words, we have to deal purely with that elusive second law of thermodynamics and not with the first. Thus, figured mechanically, the work necessary to separate five volumes of air at atmospheric pressure into one volume of oxygen and four volumes of nitrogen each at atmospheric pressure is simply that of bringing each of the partial pressures of the two gases as they existed in the mixture up separately to that of the original mixture. Or it is the work necessary to compress the oxygen from the five volumes at $\frac{1}{5}$ atmosphere to one volume at one atmosphere plus that to compress five volumes of nitrogen at $\frac{4}{5}$ atmosphere into four volumes at one atmosphere, all isothermally. Or, to put this even more concretely, if our heat interchanges and stills were thermodynamically perfect in their operation it would only be necessary to compress the original air isothermally to a pressure of approximately 10 lb. per square inch above atmospheric, to effect its complete separation into pure oxygen and pure nitrogen each at atmospheric pressure. Per ton of oxygen separated this figures out 60 hp.-hr. on the basis of isothermal compression. This is, of course, the theoretical limit for a perfect reversible cycle, which cannot be attained in practice, but we may hope to approach it to much the same degree that we have the corresponding limit in the steam engine and the air compressor, say 50 per cent as at least a legitimate goal for early endeavor. It seems doubtful whether any large scale air separating plants at present in service are greatly exceeding 10 per cent. But even 10 per cent would mean oxygen at a power cost of only 600 hp.-hr. per ton, which in itself should present startling possibilities to the minds of most chemists and metallurgists.

Magnitude of the Project

But why has there not been more actual development? This is chiefly due, I believe, to the very magnitude of the project, requiring as it does the closest co-operation and support of the whole undertaking from both

[1] "The Liquid Air Plant of the Chemistry Department, University of California," *California Journal of Technology*, Vol. 6, No. 1, pp. 1-11, Sept., 1905. "On Air Liquefiers," *Journal of Physical Chemistry*, Vol. 10, No. 4, pp. 264-274, April, 1905.

the users and producers of the oxygen. The transition from the present bottled oxygen stage of the industry to that of production directly at and as a part of the large metallurgical plant let us say where it is to be used means not only a complete redesign and development of larger production units but a complete reorganization of sales and business policy probably representing a licensing of equipment rather than manufacture and sale of product, a procedure which, to a well-established business concern, presents many drawbacks and dangers to its existing business. On this very account, the metallurgist on the other hand has never had the firm offer of oxygen in quantity and at a price to be within possible range of his operations except for such purposes de luxe as acetylene welding and burning out frozen tap holes; consequently he has never felt justified in the expensive development of oxygen or enriched air furnaces which, if successful, would in all probability necessitate very fundamental alterations in both equipment and practice.

Some Experiments in Belgium

Some experiments in this direction were indeed undertaken in Belgium before the outbreak of war, but were on an entirely inadequate scale to furnish conclusive results and, from the nature of the problem, its solution is bound to be an expensive undertaking, but one fully justified by the prospects of results attainable.

Let us consider for a moment the tremendous efforts already expended to concentrate up to the limit the ores and all the other raw materials entering a furnace and then remember that we are still adding the oxygen with four times its weight of inert nitrogen, all of which reduces the intensity of the chemical reactions and causes waste of valuable fuel, to say nothing of additional expenses due to excessive size of equipment.

But to return to the narrative. It was in March, 1916, that Director Manning of the Bureau of Mines handed me a memorandum of a conversation he had chanced to have in New York with some business men concerning a new process for air separation. The information had filtered through several non-technical hands until it had become more amusing than instructive; but, as it gave some definite addresses, I filed it with similar "clues to great inventions" and later tried to run it down to see if it had any foundation. The trail led me back with some little wandering to Mr. Fred E. Norton of Worcester, Mass., a graduate in 1891 of the Massachusetts Institute of Technology, who had since had responsible engineering experience pretty much all over the world, and I at once became interested in earnest.

Experiments Continued

His story for our present purpose begins with his leaving the position of chief designer of the turbine department at the Lynn works of the General Electric Co. in 1913, to enter the employ of Mr. E. A. W. Jefferies and undertake the engineering development of a process of air separation patented by the latter and which he had made arrangements with the General Chemical Co. to try out at one of their plants. After spending between $50,000 and $100,000 on this project the General Chemical Co. decided to drop it. Messrs. Jefferies and Norton then pooled their patents as the Jefferies-Norton process and, with the financial help of a few friends, continued experimental development in a smaller way for the next few years.

The parts of their process particularly attracting my attention were those Mr. Norton had introduced after cessation of the work at the General Chemical Co. and which radically changed the fundamental cycle upon which he in common with others had been working previously.

Scepticism Evidenced by Many

I found that, after making application for patents, they had discussed the work very freely with those who should be best able to judge of its merits and possibilities, but had made little progress toward securing practical and financial backing toward large-scale development. On attempting to investigate this situation, I found all sorts of impressions and rumors abroad as to just what the system really was. Many of those I talked with seemed to look upon it as a sort of perpetual motion scheme and were sure there was a flaw in the reasoning somewhere, although they had never run it down themselves, but understood that this one or that had done so. I had a good deal of work and not a little incidental amusement in following back to their source most of these clues and finally satisfied myself that if there really was anything fundamentally impossible in the cycle no one of those I was able to reach had been able as yet to put his finger on it.

Following our custom in the Bureau in such cases, an effort was made to put Mr. Norton and his associates in touch with people who might have sufficient use for such a process to justify their aiding in its further development, but for the reasons above cited I fully realized the difficulties and uncertainties in the way of definitely securing such co-operation.

Investigation in England

At the same time as the above development, but quite unknown to me, another thread of the present story was being spun in England. It so happened that Dr. R. B. Moore, now of the U. S. Bureau of Mines, had worked with Sir William Ramsey in his ever-memorable investigation on the rare gases of the atmosphere. Under date of Feb. 28, 1915, Sir William wrote to Dr. Moore:

"I have been investigating blowers, i.e., coal damp rushes of gas, for helium for our Government. There does not appear to be any in our English blowers, but I am getting samples from Canada and the States. The idea is to use helium for airships."

Importance of Helium for Airships

The importance of this proposed use of helium for balloons and particularly for airships of the Zeppelin type lies in the absolute inertness and non-inflammability of helium and the fact that it is of all known substances the next lightest to hydrogen, having about 92 per cent of the latter's buoyant effect. It also shows only about half the rate of diffusion and consequent wastage through the balloon fabric. As the fire hazard not only from incendiary bullets in war but also from atmospheric electricity and the Zeppelin's

power plant in both peace and war has constituted the greatest drawback to the development of lighter-than-air craft, it is difficult to overestimate what an available supply of this gas may eventually mean in the art.

At the time of the receipt of Sir William's letter the United States was not as yet in the war and nothing immediately came of the suggestion in this country. Dr. Moore remembered, however, that in 1907 Dr. H. P. Cady of the University of Kansas had found more than I per cent of helium in some natural gases from Kansas.

Dr. Moore's Letter

In a recent letter Dr. Moore says:

In April, 1917, when we entered the war, Sir William Ramsey was dead. Two or three weeks after war was declared, I attended a meeting of the American Chemical Society in Kansas City.[2] At the general session Mr. Seibel of the University of Kansas, who had been working with Dr. Cady, gave a paper on krypton and xenon in some of the natural gases of Kansas. At the end of his paper he expressed regret that at such a time, when every one was thinking of war problems, his paper was of a purely scientific nature and had no practical bearing on the war. I immediately got up and said that I did not agree with Mr. Seibel; as the presence of helium in these wells could, and should, have a very practical bearing on the war; as this gas could be extracted in quantity from the natural gas and used for balloons and Zeppelins. I pointed out some of the natural advantages of helium over hydrogen, and quoted Sir William Ramsey's letter. The general attitude of those present was one of scepticism, and I finally asked Dr. Cady for his opinion. He stated that he believed the thing could be actually done, but was very doubtful whether it could ever be made practical on account of the cost. At the close of the session Mr. Seibel came to me and asked if I really meant what I said, or whether I was joking, and I told him that I most certainly meant every word that I had said.

That same day I talked to Dr. Parsons, who was present at the meeting and who was returning to Washington almost immediately. I told him what had happened, and told him that I believed the matter should be taken up by the Bureau at once and presented to the War Department. He promised that he would do this as soon as he got to Washington; and I know that he did take the matter up with other Bureau officials.

News of Ramsey's suggestions also reached this country through other channels and eventually came to our attention. Professors Satterly and Patterson of the University of Toronto commenced experimentation on the subject Jan. I, 1916. Col. G. A. Burrell, who headed the research department of the Gas Warfare Service at the American University, tells me that Cady's experiments had also suggested similar possibilities to him.

U. S. Balloon Service Interested

However, no definite step toward securing action seems to have been taken in the United States until June 1, 1917, on which date Messrs. Moore and Burrell, at the time both of the Bureau of Mines, called on Colonel Chandler, in charge of the balloon service for the Army, and explained the whole subject to him. He was intensely interested, at once realizing its potentialities and asked that a report be made to him, giving all available details. He also took the matter up with Mr. G. O. Carter, in charge of hydrogen plants for the Navy, who had had several years' practical experience in the Linde Air Products Co. with the liquefaction and separation of gases by their process. Mr. Carter also immediately appreciated the importance of the subject and urged this upon the attention of his superiors in the Navy.

Up to this time in the whole world there had probably not been more than 100 cu.ft. of helium separated as a pure gas and its price in the small lots in which it was sold was at a rate of about $1700 per cu.ft.

About this time I was called into the conferences and was much impressed by the weight which the British Admiralty apparently laid upon the cost of separation of the gas as a determining factor in its practical availability. I was given to understand that they had figures on the basis of the well-known commercial processes of gas by liquefaction and separation and were unable to see how production could be hoped for at less than $60 to $80 per thousand cubic feet, which they felt to be practically prohibitive for the program they then had in mind. It was at this stage that I suggested turning to Mr. Norton at least for a plan and estimate of what he thought might be accomplished along the new lines he had been following, and we accordingly wired for him. On Monday, June 4, we spent practically the whole day in thrashing out the subject with Mr. Norton, Mr. T. B. Ford[3], then in charge of the low temperature laboratory at the Bureau of Standards, and Mr. O. P. Hood chief mechanical engineer of the Bureau of Mines. As a result, Mr. Norton was asked to act as a consulting engineer of the Bureau of Mines and prepare plans and estimates for an experimental plant.

Dr. Moore then returned to his station at Denver; shortly thereafter I left on a several months' circuit of our Western experiment stations, and the supervision of the project for the Bureau of Mines devolved entirely on Mr. Burrell.

Appropriation Made for Work

In due course a formal report made by the Bureau of Mines was transmitted through Secretary Lane to the War Department, and although this report was as yet fragmentary and based on very inadequate data concerning the practical conditions to be met in the field, the Aircraft Board, on July 31, 1917, recommended an allotment of $100,000, half each from the Army and Navy, which became available for the use of the Bureau of Mines on Aug. 4.

A detailed survey of field conditions, to determine the best available supply of natural gas for the purpose, was at once begun, as also the preparation of working drawings for the experimental separation plant.

The general supervision of this was for a short period at this time placed in the hands of Prof. W. H. Walker of the Massachusetts Institute of Technology, who had come to Washington to assist in the chemical warfare work. I believe it was his suggestion, for purposes of military secrecy, to use the word "argon," as a code term for helium, in all correspondence on the subject, it being thought that as real argon is also an inert gas, but too heavy to be of any value in balloons, and is already used to a large extent in the incandescent electric lamp industry, this would serve as

[2]April 10 to 14.

[3]Mr. Ford not only rendered valuable service in these early conferences but took a most helpful and important part throughout the later stages of the work, both at the Bureau of Standards and in a trip he made to the plants in Texas and was engaged on this work when suddenly stricken down a few months ago with influenza. His death came as a shock to us all, terminating as it did a career of great promise.

particularly effective camouflage. This has in fact so effectively confused the two words in the public's mind that it will take some little effort to clear up the situation, and I would therefore bespeak your help in holding strictly to the true name helium whenever referring to the subject, now that all secrecy in the matter has been abandoned.

Even though we had been drawn into this work primarily through the desire of the British authorities to find a more economic process than those already known to them, it was now felt that the project had taken on such magnitude that the whole field should be carefully canvassed *de novo*. Mr. Burrell therefore next communicated with the two well-established operating companies controlling, respectively, the Linde and Claude systems of gas liquefaction and distillation, to determine whether it would be possible to work out a plan of general co-operation and pooling of information and facilities for this specific war purpose. Due to questions of trade secrets and other business relations, this did not, however, prove practicable, though both companies expressed themselves as anxious to co-operate individually with the Government and entirely willing to undertake independently the erection of plants of their own respective designs at cost, or even less, and have ever since most cordially furnished every aid in their power to make the work as a whole a success.

British Send Commission

At this juncture a special commission from the British Admiralty, headed by Commander Cyprian D. C. Bridge, arrived in this country to collect data and exchange ideas on what was being done, and from the resulting conferences the possible importance of the work in hand became so evident that the Aircraft Board on Oct. 17, 1917, recommended that a further allotment of $500,000 be made jointly by the Army and Navy to permit of immediately starting construction of complete plants under all three processes.

In accordance therewith, Mr. Norton was directed to prepare plans for a somewhat more complete plant embodying his process than had originally been contemplated as a first step. This brought the total estimated cost of the plant to about $150,000.

Norton Project Sidetracked

In making the actual allotment, however, the Navy placed a restriction upon its half of the $500,000 that none of it should be used on the Norton project. When this was called to the attention of the Army the latter decided to follow the Navy's lead, as they were very largely relying upon it for guidance and had designated Mr. Carter to represent them jointly in the matter.

Thus, while thoroughly realizing the expediency of the Navy's policy in making sure that the plants under established processes should be adequately financed and pushed with all possible rapidity to completion, the curtailment of support for the newer and more experimental portion of the program was a disappointment to those of us in the Bureau of Mines who had made a careful study of the Norton project and felt strongly as to the importance of giving it a thorough trial. The representatives of the British Admiralty also stated frankly that their main interest lay in the experiments on this process, as there was no particular doubt in their minds that either of the other processes could produce the gas, the only question being one of cost, and on this no one responsibly connected with either of the two old processes had been willing to even hold out any definite hopes of producing helium below the cost of $80 a thousand cubic feet, which the Admiralty at that time considered prohibitive for its chief purposes. The matter was consequently taken up afresh with the Aircraft Board and after considerable discussion that body on Dec. 11 recommended to the Army and Navy a further joint appropriation of $100,000 specifically for the Norton project. The Army immediately acquiesced with regard to its half but the Secretary of the Navy, feeling the need of further outside advice in the matter, requested the National Research Council to investigate the project with special regard to its theoretical soundness and its apparent chances for practical success.

Committee Appointed

The Council appointed for this purpose a committee of five consisting of Prof. Harvey N. Davis of Harvard University, Drs. Edgar Buckingham and Charles W. Waidner of the Bureau of Standards, Dr. W. S. Landis of the Air Nitrates Corporation and Mr. S. L. G. Knox, consulting mechanical engineer and later scientific attaché of the American Embassy at Rome. This committee after very careful comparative study of the three processes concurred in the Aircraft Board's recommendation of the additional $100,000, which was then immediately made available by the Army and Navy.

This was early in February, 1918, the controversy over the support of the project having delayed the actual starting of construction on the Norton plant by something over two months.

In the meantime contracts had been closed with the Linde Air Products Co. and with the Air Reduction Co. for the construction and experimental operation of a Linde and a Claude plant respectively, each for an estimated daily production of about 7000 cu.ft. of helium, and construction was well along on each. These plants were to be located at North Fort Worth, Texas, and operate on a natural gas containing about 0.9 per cent by volume of helium and of which the Lone Star Gas Co. was bringing some 20,000,000 cu.ft. daily through its pipe line from the wells at Petrolia, more than a hundred miles northeast of Fort Worth, to that city for domestic and industrial consumption.

After careful study of field conditions it was decided to locate the Norton plant at Petrolia in direct proximity to the wells, a procedure which had not been deemed practical for the two other plants on account of their larger demands for power and water supply.

Other Investigations

Parallel with the Bureau of Mines work on processes of extraction, Dr. A. F. Rogers of the U. S. Geological Survey undertook a recognizance of all natural gas fields in the United States with regard to their possible helium supply, as this might be judged from sampling and analysis of existing wells combined with a study of geological conditions. As the results of this study are expected to soon be issued as a monograph by the Survey, no attempt will be made to deal with them here.

The Bureau of Standards also undertook the determination of certain physical properties of the gases. More especially the latent and specific heats and specific volumes of methane over a wide range of pressures and temperatures, and the diffusion of helium through balloon fabrics.

In order to co-ordinate properly all the different agencies concerned, the conduct of the helium work as a whole was about this time placed in the hands of a committee consisting of one representative from each of the three departments chiefly concerned. Mr. G. O. Carter, as chairman, represented the Navy, Dr. Harvey N. Davis the Army, and Mr. Geo. A. Orrok the Interior.

Quantity and Purity Increase

The Linde plant, costing in round figures $300,000, was the first to be contracted for and have its construction started. It commenced operation March 6 and on March 22 produced gas containing 28 per cent helium. By April 21 this purity had reached 50 per cent, the yield being at first small, but both quantity and purity steadily increased up to a maximum daily production on Sept. 6 of 7755 cu.ft. of 67 per cent purity, with average production of say 5000 cu.ft. at over 70 per cent purity, which was then further purified in a second step to about 92 or 93 per cent purity.

The Claude plant, costing about half as much as the Linde, commenced production some weeks later than the latter, and has also gradually increased its production and purity of product. Although up to date these are still considerably behind the performance of the Linde plant, a new still is just being installed at the Claude plant which it is hoped will materially improve both yield and purity of the product.

Due to present pipe line limitations coupled with heavy consumption of fuel gas at this time of year, it has been necessary for some months past for the Lone Star Gas Co. to substitute for part of the Petrolia gas some from other fields carrying less helium, so that the helium content of the gas at present being treated at Fort Worth has fallen to between 0.4 and 0.5 per cent by volume, which proportionately cuts down the production at both plants.

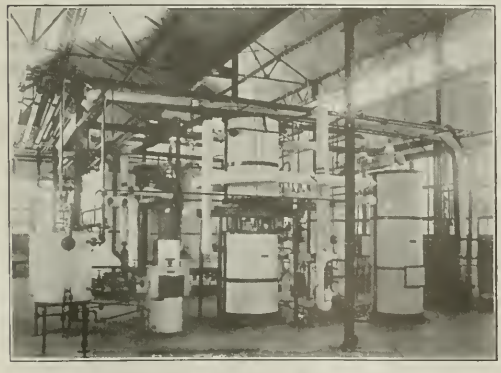
At the time of signing the armistice the first shipment of 147,000 cu.ft. of 93 per cent helium was on the dock about to be loaded aboard ship for Europe. This at the above-cited pre-war prices would represent about $250,000,000 worth of gas.

A large part of the credit for the promptness with which this actual production was affected is due to Mr. Carter, who was tireless in his efforts in pushing matters of priority, transportation, construction and production.

The Army and Navy have now jointly entered upon a larger production program under the immediate direction of the Navy, and have allotted some $5,000,000 for the purpose, including the construction of a new pipe line and additional units of the Linde plant at Fort Worth. General Squire, in an address before the American Institute of Electrical Engineers last week, stated that "Plants are under construction to give at least 50,000 cu.ft. a day at an estimated cost of not more than 10c. per cu.ft." If present expectations of the Norton process are fulfilled, this cost may be still further greatly reduced.

The Norton, or Bureau of Mines, plant at Petrolia was completed as far as initial construction is concerned the middle of October, and since that time its various parts have been successively undergoing tests and adjustments. The multi-tubular heat interchanges and large expansion engines, which were among the new departures in this plant, over which most anxiety was originally felt, have thus far worked out very well and now seem to be performing their allotted tasks to complete satisfaction. A good deal of difficulty was at first encountered by occasional floods of several barrels of oil and salt water coming over from the Lone Star Gas Co.'s gasoline extraction plant, which immediately clogged up the interchanges, making it necessary to shut down and go through the laborious process of thawing out the whole system and starting refrigeration afresh. This has now been eliminated by the installation of adequate settling chambers and traps, and tests and adjustments are proceeding upon the stills which form the last part of the equipment to be proven out. It is hoped that helium production will soon be attained, but as this plant has a rated production capacity of several times that of either of the other two, each change or adjustment in its parts requires rather more time even aside from the fact of the entire novelty and experimental character of many of its parts.

In studying the different systems of gas liquefaction



INTERCHANGE AND STILL ROOM OF LINDE PLANT

and separation it is very essential at the outset to distinguish clearly between the production of liquid as an ultimate product and the utilization of liquefaction and re-evaporation as a mere step in a separation where the ultimate products desired are still gases and at essentially the temperature of the original mixture fed to the apparatus.

In the former case a very considerable expenditure of work is represented in what we may colloquially term the refrigerative properties of the liquid delivered.

But in the second case, where the liquid is not drawn off from the apparatus and its amount therein remains constant, the part continually evaporating serves to condense nearly an equivalent amount of the incoming gases. Also the cold gases furnished by this evaporation take up heat from and cool the fresh incoming gas while they themselves are returning to room temperature.

Ideal Equal Pressure Process

Thus we may illustrate diagrammatically, as in Fig. 1[1], the continuous process of liquefaction and re-evaporation of a single gas. Ideal conditions would consist in perfect heat interchange horizontally between the two legs of the U tube A and C and perfect heat insulation lengthwise along each of these and from their surroundings.

If these conditions were fulfilled and the whole system once brought to a steady state by, let us say, refrigeration of the bottom of the U tube by some extraneous source of initial cooling while gas was slowly passed through it, we may imagine a certain amount of liquid condensed at the bottom of the U and a uniform gradient of temperature established along its two legs. Now, if the initial extraneous source of refrigeration were removed but gas still passed slowly into the system, the gas would progressively cool in A, liquefy at B, re-evaporate at B_2 and warm back to the atmospheric temperature in passing up C. Under these ideal conditions, with a single gas, the slightest imaginable difference in pressure between A and C should serve to perpetuate the process.

[1]The four cuts here shown are from a report made in the early part of this work by Mr. Norton to Mr. Burrell, outlining the problem in hand and the relation of the three processes to one another as they appeared to him.

Whatever heat leakage there is, however, either through the walls of the insulating chamber or down the legs of the U tube, represents a loss not of energy itself but of its availability for the purposes in hand; i. e., of thermodynamic potential, or an increase of entropy, if one prefers that terminology, the practical result being the necessity of expending mechanical work to compensate for these heat leaks. If, in addition to this, we are dealing with a mixture instead of a single pure gas, the constituents will in general liquefy and re-evaporate with varying ease, tending to set up temperature differences between adjacent parts of the two legs of the U and thus requiring a further expenditure of work to operate the cycle.

Looked at from the point of view of gas separation, the first of these effects represents pure loss, but the second is due, at least in part, to overcoming what we have above termed the force of diffusion in separating the gases and should thus be counted as useful work.

The problem is, therefore, to provide just enough refrigeration *at the proper temperatures and places* to cover these two demands after they themselves are reduced to as low a value as possible in the design of the apparatus and by use of the best heat insulation attainable.

The three systems for gas separation now before us differ perhaps most strikingly of all in the way in which they produce this refrigeration.

In the case of the Linde, Fig. 2, the gas mixture to be

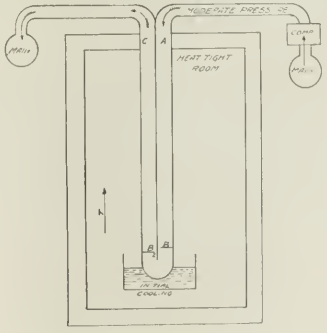

FIG. 1. IDEAL EQUAL PRESSURE

separated is pumped at very high pressure (say 1500 to 3000 lb. per sq.in.) into leg A and simply allowed to expand through a regulating throttle to a lower pressure at B_2 and return through D, the refrigeration being usually credited to the "Joule-Thompson effect." A discussion of this latter here would carry us too far into theoretical physics, but it may help the uninitiated in such matters to picture intelligently the general effect of this process to say that the specific heat of highly compressed gases is usually less than that of the same gas at lower pressure, so that a given weight of gas passing down leg A under high pressure in falling from one temperature to another will give up fewer calories

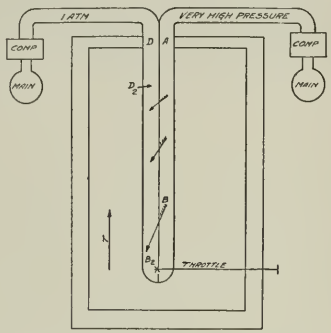

FIG. 2. LINDE SYSTEM, SELF-COOLING

of heat than the same weight of gas coming up the leg D will absorb between the same two temperatures. Thus it is evident that on the whole more heat will be carried out of the system by the issuing gas than is brought in by the incoming, with resulting refrigeration.

The fact that these differences of specific heat only become important at considerable pressures and the pressure created for this purpose is practically wasted at the throttle, as far as useful mechanical effect is concerned, makes this process decidedly inefficient from a thermodynamic standpoint; i. e., from the question of power consumption. Its chief merit lies in its extreme simplicity and freedom from moving parts. It is the type of system first developed both in the laboratory and commercially. As cooling proceeds, liquid finally forms at B_2. For the purpose of separating the constituents of the mixture the leg D is developed into a "column still" on the same principle as those used for rectification of ordinary liquids, but, to avoid confusion, not shown in the present cuts.

The Claude System

In the Claude system, schematically represented in Fig. 3, another principle is introduced. It was early pointed out by Lord Kelven and others that if some sort of expansion engine could be substituted for the free expansion throttle in systems of the Linde type and the work of these engines expended outside the heat-tight room, greater refrigerative effect would be produced even if all the mechanical work so produced were allowed to go to waste, for in its mere production it would have already extracted an equivalent amount of heat from this room. As, for the purposes in hand, these engines must work at very low temperatures, grave mechanical difficulties were seen in the problems of lubrication, brittleness of valves, stoppage by frozen impurities from the gas and the like. George Claude of Paris was the first to solve these difficulties, at least in a commercial way, and his book[5], recounting his experiences and discussing the general theory of the subject, is intensely interesting.

By use of an expansion engine, Claude was able to drop the initial gas pressure to from 400 to 600 lb. per sq.in., or even lower in some of the larger units recently erected for air separation. At these pressures the effect depended upon by the Linde system practically disappears so that, in practice, the Claude system works essentially on a wholly new principle rather than by the superposition of this upon that of the Linde process.

However, as Claude confined himself to one expansion engine[6], it was necessary for him, with his moderate initial pressure, to locate the engine's gas intake at a level in his interchanger sufficiently low so that the exhaust would reach the lowest temperature desired in the system and still be able to absorb quite an appreciable amount of heat at this temperature.

With the one engine taking its gas from the incoming side of the U, it is also evident that for efficient liquefaction only a part of the gas can be expanded through the engine, for, if liquefaction takes place in its cylinders, expansion to that extent is lost. The remainder of the gas must, therefore, be retained under pressure in the U and cooled down and liquefied by heat exchange with the expanded gas returning as indicated

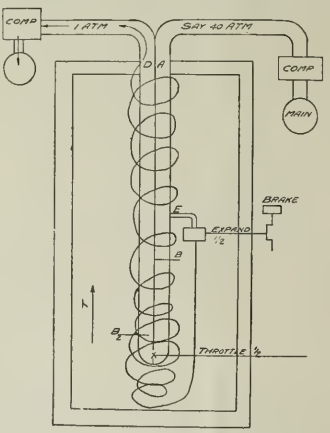

FIG. 3. CLAUDE SYSTEM, EXTERNAL WORK FOR COOLING

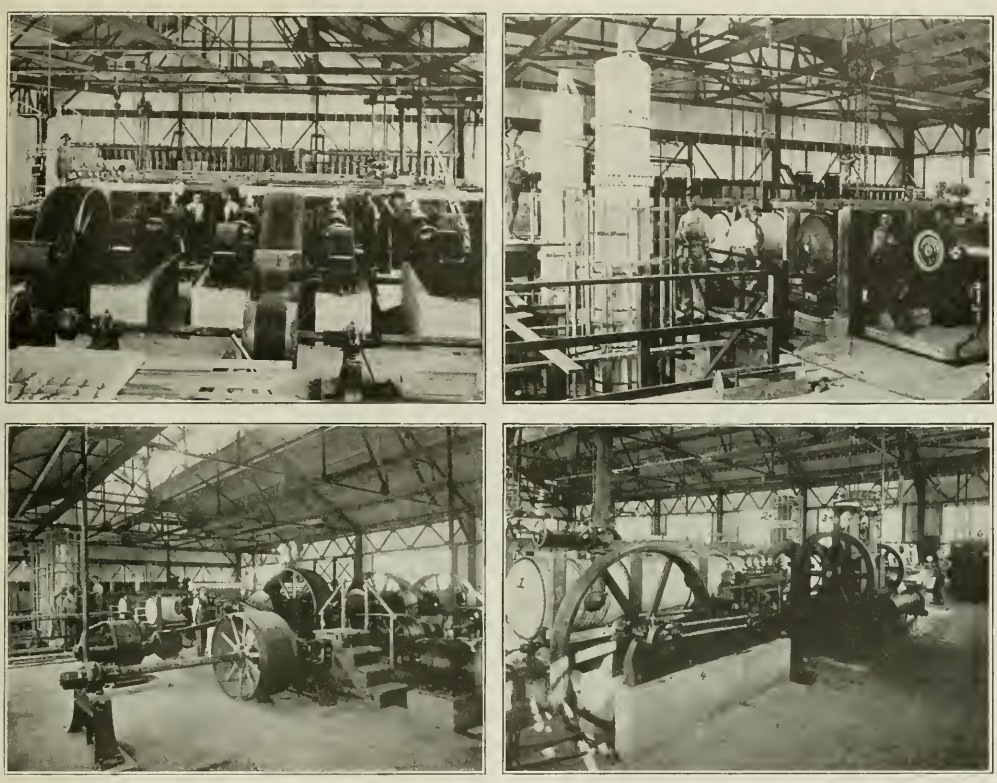
by the spiral line around both legs of the U. The gas after liquefaction in leg A is let into leg D through the throttle and there under the lower pressure rapidly drops still further in temperature by its own evaporation. Here it undergoes fractional distillation as already explained above.

The Jefferies-Norton System

Coming finally to the Jefferies-Norton system, Fig. 4, it will be noted that this differs from the Claude in

[5] "Liquid Air, Oxygen and Nitrogen," published by P. Blakiston & Co., Philadelphia.

[6] Though this is in many cases compound, having a high and a low pressure cylinder.



BUREAU OF MINES (JEFFERIES-NORTON) PLANT AT PETROLIA

Top left—Expansion engines. Top right and bottom left—General interior views. Bottom right—1. Interchanger. 2. Still. 3. Vacuum pump. 4. High pressure compressor for bottling finished gas. 5. Gage board. 6. Switchboard.

at least three important points, viz.: (1) The system employs more than one engine (in the illustration three, AE, BE and CE), each working through a different temperature range. The number of these temperature steps depends upon conditions, increasing with the total range of temperature to be covered and also with decreasing initial pressure employed. (2) The pressure in the outgoing leg of the U is only enough lower than in the incoming leg to allow for proper control of flow, unavoidable friction, head of liquid in the still trays and the like. (3) The engines work upon the gases after their liquefaction and distillation, thus permitting all the gas to be so treated. Incidentally, this also insures freedom from easily frozen impurities entering the engine valve chambers and cylinders and in many cases greatly simplifies the whole problem of initial purification of the gas to be treated. Engine C corresponds in a way to Claude's one engine system but as the initial pressure used in the system can, on account of its greater efficiency, be much less than in the Claude, the temperature range over which this engine works will be much less than in the latter. Since, when expanding a given weight of gas between two definite pressures, the work obtainable from it (and consequently the number of calories its expansion will extract from the system) is greater the higher its temperature, engine A will extract the most heat from the system and deliver the most power to the crankshaft per unit of gas used and engine C the least, which still further emphasizes the importance of this development.

Rough analogies, though suggestive, are often danger-

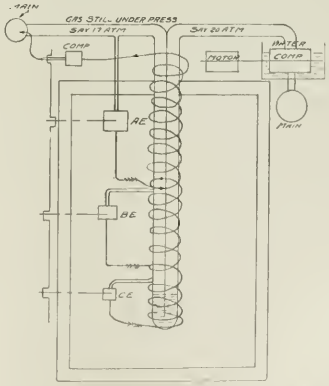


FIG. 4. JEFFERIES-NORTON SYSTEM, TEMPERATURE COMPOUNDED

ous to accuracy in scientific and technical explanations, but without laying any great stress upon it, the following may here be helpful to those not especially familiar with this subject. It was pointed out at the start that a considerable amount of the refrigerative effort which has to be expended in any of these processes is to remove the heat which, despite the best insulation we can put on the apparatus, still leaks in from without. Now in this sense the expansion engines of the last two processes may be thought of as engaged partly in pumping out this heat from the refrigerated system back to the outside, much as mine pumps are kept busy pumping out the water which leaks into a mine. Just as water may be coming in at various levels in the mine, so heat is leaking in to parts of the system at all levels of temperature. The one engine of the Claude system is analogous to the mine with a single pumping station at the very bottom where all water entering at any part of the mine is allowed to drain clear to the bottom and is then all pumped from there to the surface, while the Jefferies-Norton system is analogous to the installation of several pumping stations at different levels so that water from the upper levels is pumped out over the shorter lifts, thus saving power.

The really salient feature brought out in these diagrams is perhaps the progressive approach toward the ideal of thermodynamic reversibility and the high degree to which this is fulfilled in the basic principles of the last system.

Engineering Council Establishes National Service Committee

IN ORDER more completely to provide for united action upon matters of common concern to engineers, the Engineering Council has recently organized a National Service Committee and has established an office in the national capital at 502 McLachlen Building, 10th and G Streets, the office of M. O. Leighton, chairman.

The Engineering Council, through this National Service Committee and its Washington office, intends to accomplish the following general purposes, this committee acting always under the direction of the council and within limitations fixed for it:

1. To discover public services which may best be performed by engineering societies, and, when desired, to offer the proper men for such services.

2. To speak authoritatively for the Engineering Council before committees of Congress and departments of the Government on all public questions of common interest to engineers, within such limitations as the council may set from time to time.

3. To give promptly wide circulation among engineers to authentic information regarding pending legislation and executive actions which may affect the interests of engineers in any way.

4. To gather opinions of engineers on these matters.

The Engineering Council's aim is disinterested usefulness to the nation and the profession—not advocacy of any selfish ends—by giving unbiased information and counsel on technical matters, chiefly when asked. A modest start is being made. The work will be enlarged only as a real demand for services develops.

Meeting of American Institute of Chemical Engineers

Review of Proceedings of the Annual Meeting, Officers Elected—Advocate Adequate Tariff Protection, Anti-Dumping Law, Proper Means for Disposition of Government Stocks of Chemicals—Plants Visited—Our Chemical Industries Made Permanent, Webb Law, Open Price Associations

SUBSCRIPTION DINNER AT CONGRESS HOTEL

THE Chicago meeting of the American Institute of Chemical Engineers, Jan. 15-18, was in a number of respects the most successful ever held by this society. The keynote of the entire meeting was well expressed in the title of the symposium held on the opening day—"The Maintenance and Preservation of Our Chemical Industries." This is the most timely and vital subject at the present time which could be chosen for a meeting of chemical engineers.

The large attendance at the meeting indicated that the importance of the topic was realized by the members of the Institute as well as by the Chicago chemists and the chemical industries that sent representatives to the meeting. The United States Government was represented by Dr. Grinnell Jones, the chemist of the U. S. Tariff Commission. The attendance at the opening session of the meeting on Wednesday morning was about 100 and reached a maximum of about 250 on Thursday evening, when Col. Alfred H. White spoke on "The Present Status of Nitrogen Fixation" and Prof. Julius Stieglitz made an address on "The Manufacture of Synthetic Medicinal Compounds." The weather throughout the meeting was fair and mild. The increasing public interest in the chemical industries was shown by the amount of space given by the Chicago papers to the meeting and the presence throughout the entire meeting of a special representative of the *Literary Digest.*

The meeting was opened on Wednesday morning by President Thompson. The address of welcome was given by Mr. Leonard Busby, president of the Chicago Surface Lines. In welcoming the chemical engineers, Mr. Busby expressed as a business man his realization of the important part which the chemical engineer had played in winning the war and developing the resources of the country and the important problems still awaiting solution.

Officers Elected

During the business session the report of the canvassing committee showed that the following officers had been elected for the coming year: President, Arthur D. Little; vice-president, Prof. Albert W. Smith; secretary, Prof. John C. Olsen; treasurer, Dr. F. W. Frerichs; auditor, Dr. Charles F. McKenna; directors for three years, J. V. N. Dorr, Herbert Dow and Hugh K. Moore.

The secretary reported a membership of 306, which is an increase of 22 during the past year. Eight applications for membership had not yet been acted upon. The membership committee reported action on 19 applications since the last meeting. Several applicants had been rejected on account of insufficient chemical engineering experience or non-conformity with the code of ethics of the institute. The treasurer reported a substantial balance and $1250 invested in Liberty Bonds.

Prof. James R. Withrow, chairman of the committee on chemical engineering education, reported arrangements for having a copy of Dr. Mann's report on engineering education sent to all members requesting it. Prof. Withrow's committee will present a full report on this very important study of engineering education at the next meeting of the institute, when opportunity will be given to discuss the report.

The committee on meetings reported invitations from Boston, Atlanta, Providence and Cincinnati for the summer meeting with the recommendation that Providence be selected for the summer meeting and that a winter meeting be arranged for Atlanta, and that arrangements be made to visit the important industrial centers in that vicinity. The entire matter was left to the council with power.

After the business session the remainder of the morning, as well as the afternoon and the evening, was devoted to papers and discussion of the important topic, "Maintenance and Preservation of Our Chemical Industries."

The address of President Thompson was devoted to this topic under the title "Chemical Industries Made Permanent, and is given in full elsewhere in this journal.

Resume of Conditions

The next speaker was Maximilian Toch, who, with L. H. Baekeland as a special committee, had arranged the symposium and invited chemical manufacturers to send representatives to the meeting. Mr. Toch presented a résumé of conditions as they exist to-day in the chemical industries. He stated that more than 2,000,000 men and women are employed in the newer chemical industries. The need for tariff protection for these industries is shown by the fact that before the war the dye azo scarlet was imported and sold for between 15 and 20 cents per pound. To manufacture this dye in the United States to-day costs 85 cents per pound, which may possibly be reduced to 65 cents if the cost of raw material and labor is reduced.

Mr. Louis Matos, representing the National Aniline & Chemical Co., emphasized the great cost of developing the method of manufacture of coal-tar dyes and stated that it would be from three to five years before reliable data on production costs could be obtained.

Mr. Robert Hilton stated that the Ault & Wiborg Co. had invested a large amount of capital in the manufacture of dyes and that it would be absolutely impossible to meet the competition of the well-established German industries unless a much higher protective tariff were enacted by Congress.

Mr. William H. Rollin of the Rollin Chemical Co. discussed "The Future of the Barium Industry" and stated that this industry is still in its infancy and has not had time to become well established or financially strong. Freight rates will also be a determining factor in the future of this industry. While railroad rates are high, ocean freight rates from Europe may become so low that importation will be stimulated. Mr. Rollin stated that the survival of the barium industry was almost entirely dependent upon a protective tariff.

Mr. Colby Dill of the Perth Amboy Chemical Works maintained that the solution of the problem could be found in more and better research work being carried out on our chemical processes, employing for this work the chemists who have been released by the Government. Mr. Dill maintained that with good team work the American chemical engineer could meet foreign competition, as he has shown himself to be more resourceful and progressive than his foreign rival.

Advocate Anti-Dumping Law

During the general discussion of these papers a drastic anti-dumping law was advocated. The licensing system adopted by Great Britain was also urged as a very effective remedy. Under this system the importation of dyes and other chemicals is prohibited when domestic manufacturers can supply the market and importation is permitted only to the extent required to supply the domestic market with chemicals not manufactured in the country or of which the production is not sufficient.

Dr. Grinnell Jones, chemist of the U. S. Tariff Commission, read a paper on "Recommendations of the Tariff Commission in Regard to Dyes and Coal-Tar Chemicals." Dr. Jones discussed the provisions of a bill proposed by the commission to Congress making 45 amendments to the bill of Sept. 8, 1916, which established a tariff which encouraged the investment of capital in an American dye industry. The proposed amendments make no radical changes in the present tariff law either as to rates or classification, but merely correct some technical errors in the present law by which the evident intent of Congress is nullified. The tariff rates would therefore remain as at present, namely, 30 per cent plus 5 cents per pound on the finished dye, 15 per cent and 2½ cents per pound on intermediates, while the crudes are on the free list.

The Tariff Commission has no power to recommend rates of duty or to determine general policy as to high or low protection or free trade. These questions must be settled by the people. For this reason no material increase in tariff is likely until after the next Presidential election. The remedy therefore for the present predicament of the chemical industries is to be found in the reduction of manufacturing costs by the work of the chemical engineer and a change in the general economic condition.

Broad Reconstruction Program

Dr. Edward Gudeman in a paper on "Reconstruction Aspects of Some Chemical Industries of the United States" urged the adoption of a very broad reconstruction program. He advocated not only protection for our newly established chemical industries, but also conservation of our national resources, both material and human, by improving living conditions, giving employment to discharged soldiers and sailors, universal education in English, economic equality and development of our transportation facilities.

At the conclusion of the discussion a set of resolutions was adopted which had been drafted by a committee consisting of President Thompson, Secretary Olsen, F. E. Dodge, F. M. Dorsey, Edward Gudeman, A. H. Hooker, H. W. Kellogg, C. Bai Lihme, Louis Matos, S. W. Parr and Maximilian Toch. The resolutions strongly urged Congress to provide adequate tariff protection, enact an anti-dumping law and also so to dispose of Government stocks of chemicals that the market may not be demoralized.

A complimentary luncheon was served on Wednesday by the local committee to members of the institute and their guests. The local committee had also arranged for a smoker on Wednesday which was well attended and very much enjoyed by all.

Corn Products Co. Plant Visited

Thursday was spent in a visit to the large plant of the Corn Products Refining Co. at Argo, Ill. Two special cars had been provided by the local committee for transportation to the plant. The party of 54 was divided into small groups for the inspection. The following members of the company acted as guides: F. M. Sayre, superintendent; C. L. Soverign, superintendent of the refinery; Harry Reynolds, foreman of the starch department; Otto Sjostrom, research chemist, and Al Peterson. The plant is the largest of its kind in the world, the daily grinding of corn being 60,000 bushels, and $1,000,000 is being spent in improvements and additions to the plant on account of the increasing consumption of corn products.

The process of separating the constituents of the kernel of corn into starch, gluten, germ and hull was first shown. The starch house was then inspected. Here the raw starch is refined and dried. The sugar refinery was then visited where the starch in 10,000 lb. batches is converted by heating under pressure in the presence of muriatic acid into dextrine or dextrose. Part of the production of this department is glucose or karo and part is 80 per cent sugar, 250,000 lb. of sugar being produced daily.

The oil house was also visited, where corn oil is expressed from the dried germs by means of Anderson expellers. The oil is refined and sold as mazola. In the feed house all by-products of the plant are converted into cattle food. The power house was also visited and its excellent condition admired by the visitors. Automatic devices for operation, control and recording of performance had been installed wherever feasible. Electric power distribution was used throughout the plant.

Luncheon was served to the party in the commodious, well-lighted and well-kept employees' restaurant. The luncheon was identical with that served to the employees for 29 cents, which is the cost exclusive of rent and maintenance of the building. The luncheon was first-class in quality and quantity.

Welfare Work Explained

After luncheon Mr. F. M. Sayre, the superintendent of the plant, explained the welfare work being carried on by the company and the plan recently introduced for bringing about satisfactory relations with the employees. This plan included the election of an advisory committee of three employees in each department. All questions relating to working conditions in the department were brought before this committee sitting with the superintendent of the department. Appeal could be taken to a general committee elected by all employees of the plant, which met with the general superintendent. This plan had worked out very satisfactorily and the excellent relations existing between employees and the superintendent were very evident during the inspection of the plant. There are employed in the plant 1900 men and 600 women.

On Thursday evening Col. Alfred H. White gave a description of the nitrogen fixation plants which had been projected or erected by the Government. Lantern slides of some of these were shown. The plan decided upon contemplates the utilization of several of the nitrogen fixation processes which had proved commercially successful.

At plant No. 1, located at Sheffield, Alabama, synthetic ammonia was produced from nitrogen and hydrogen by a modification of the Haber process. The contemplated capacity of this plant was 60,000 lb. of ammonia daily, half of which it was planned to oxidize to nitric acid in order to produce ammonium nitrate. One unit only of this plant has been operated. The second plant, located at Muscle Shoals, utilized the cyanamide process and was designed to produce 110,000 tons of ammonium nitrate. This plant will be closed Feb. 1 until Congress shall determine what disposition shall be made of it. Plants 3 and 4 were located at Toledo and Ancor, Ohio, and were cyanamide plants. A 10-ton experimental plant had also been erected at Saltville, Va., to try out the Bucher process of producing sodium cyanide.

Prof. Julius Stieglitz then addressed the institute on the subject, "The Production of Synthetic Medicinal Compounds," Prof. Stieglitz explained how progress had been made in the study of the effect of specific organic groups or radicals on the human system and urged that more attention be given by chemists to this important field of research. He mentioned the production of synthetic adrenalin, which can be injected directly into the blood and which in 25 minutes will give effective relief to asthma patients.

Other Papers Read

At the Friday morning session the following papers were read and discussed: "Reinforced Concrete Tanks for Storing Ammonia Liquors," by F. W. Frerichs; "Concrete as a Chemical Engineering Material," by Maximilian Toch. In both of these papers methods of rendering concrete proof against erosion, chemical action, disintegration and decomposition were given. A paper on "Some Wild Engineering I Have Known" was read by David Wesson. A paper on "Chemical War Secrets and Manufacturers' Rights," by Edward Gudeman, emphasized the care which must be taken by Government officials not to divulge manufacturing secrets given them for war purposes.

"Belting for Power Transmission," by Ernest D. Wilson, brought out a very interesting discussion on this subject. Mr. Wilson presented the results of experiments showing that in most instances leather belting is the most efficient for power transmission.

After partaking of another complimentary luncheon furnished by the local committee, members and their guests proceeded by auto to the plant of the Lindsay Light Co., where the entire process of manufacture of incandescent mantles was shown. A new method had been worked out for the manufacture of thorium and cerium nitrates from monozite sand. The preparation of the fabric mantle, as well as the impregnation and burning off of same, was shown in detail.

The Underwriters' Laboratories of Chicago were then visited. The great variety of tests, both physical and chemical, which are carried out in this laboratory was

surprising. A great deal of interest was shown in the fire tests which were made on complete building walls cosntructed of various fire resisting materials.

The subscription dinner was held on Friday evening at Congress Hotel. About 60 covers were laid. The first number of the after dinner program consisted of several vocal selections by Mme. Myrna Sharlow of the Chicago Grand Opera Company.

Mr. Arthur Lowenstein introduced the well known poet and humorist, Mr. Wilbur D. Nesbit, as the toastmaster of the evening. The audience was kept in a roar by Mr. Nesbit's sparkling wit and humor. He first introduced Dr. L. V. Redman, chairman of the Chicago Section of the American Chemical Society, who spoke on "Why Is a Chemical Engineer?" "The Problems of the Chemist as Seen by a Layman" was responded to by Vincent Rockey of the research department of the *Literary Digest*. Mr. Rockey spoke of the great change which has come in American public opinion from indifference to intense interest in chemical topics. Dr. Grinnell Jones spoke of the work of the Tariff Commission. President Thompson was given the topic, "Chemical Horse Sense," and ingeniously drew many parallels and contrasts between the chemist and the most intelligent and faithful of domestic animals.

Secretary Olsen was called upon for a toast to "The Future of the Institute." While denying any ability as a prophet, Dr. Olsen asserted that if the institute did its work with the same energy and success displayed by the local committee in preparing for the Chicago meeting its future would be very bright. Speaking on the subject "Some Chemical Fakes I Have Met," David Wesson told of a number of very amusing incidents he had experienced.

On Saturday morning a number of the members visited the plant of the Standard Oil Co. at Whiting, Ind. This plant has been practically rebuilt during the last three years.

The number of ladies present at the meeting was not as large as at previous meetings, but those who were present were royally entertained. The program included a theater party on Thursday evening and grand opera at the Auditorium on Wednesday evening, as well as an auto trip through Chicago's park system. The ladies were also present at the luncheons on Wednesday and Friday and also at the subscription dinner on Friday evening. The members of the local section of the American Chemical Society participated in all sessions and functions of the meeting and materially assisted in making the meeting a success.

The committees were as follows:

General chairman, F. M. de Beers.

Finance Committee—A. W. Ayers, chairman; C. F. Hagedorn, G. N. Prentiss.

Entertainment and Reception Committee—F. W. Willard, chairman; C. B. Lihme, Edward Gudeman, Arthur Lowenstein.

Excursion and Transportation Committee—Harry McCormack, chairman; William D. Richardson.

Papers and Meetings Committee—L. W. Andrews, chairman; G. H. Pickard.

Publicity Committee—William Hoskins, chairman; P. B. Sadtler.

Ladies' Committee—Mrs. W. D. Richardson, chairman; Mrs. G. W. Willard, Mrs. Millner.

Our Chemical Industries Made Permanent

By G. W. Thompson*

DURING the last four years our chemical industries have had a wonderful opportunity to lay the foundation for a permanent development. This opportunity was occasioned through the cutting off of foreign competition and also through the abnormal demand created by war conditions. This period has passed and we are now on the threshold of another era, an era of readjustment, an era calling for the greatest intelligence and activity of mind if what already has been accomplished is to develop into a permanent industrial gain. To solve the problem of making our chemical industries permanent, it is necessary to study carefully the conditions that are confronting us so that means will be devised for properly meeting them.

There are certain things that can be eliminated from consideration at once. The production of chemical products having practically only war uses must cease. It is to be presumed that no one would advocate the continuation of wars in order that these products should continue to be produced. The proper study should, of course, be made to find out how the chemical products needed for war purposes can be used for peace purposes. It seems improbable, however, that much can be done in this direction. Of course much of the apparatus used in the production of munitions of war can be used in the production of those things needed in peace, and to that extent such industries can be modified and put, as it were, upon a peace basis. It is presumed, also, that in those industries established or developed for purely war purposes, a conservative policy has been followed so that the plants have been more or less paid for from war profits. If this conservative policy has not been followed, I know of no means of preventing financial loss. Such industries should take their losses and start in again on a new basis, manufacturing, if possible, peace products.

Let us consider now the problems that confront the manufacturer of chemical products for which there is a peace demand. We will attempt to list these problems and then proceed to analyze them more fully. As we see it, these problems are: first, how to meet foreign competition; second, how to correct destructive domestic competition; third, how to meet the losses which may result from falling prices, should falling prices come as is expected by many; fourth, how to meet the problem of high wages, with the probability of their also falling; fifth, how shall our chemical industries more intimately organize for peace production.

Foreign Competition

Judging by the expressions of opinion which have so far appeared in the chemical journals, foreign competition presents the most serious problem. The greatest difficulty, however, that arises in considering this problem lies in what we may expect under this heading. There are many diverse views. Some seem to think that Germany will, as soon as possible after peace is declared and the avenues of trade are opened up, commence to dump manufactured chemicals upon the markets of the world. German competition in the past has been considered unfair competition, and it is claimed, with-

*Address delivered at the Chicago meeting of the American Institute of Chemical Engineers, Jan. 15, 1919.

out contradiction and perhaps, on the other hand, without sufficient confirmation, that she followed the deliberate practice of selling goods under cost in certain markets until the local concerns supplying those markets were compelled to give up business, and when this result was obtained the price of the German product would be raised higher than the domestic product had been sold for. The Germans would continue to hold the market, as domestic manufacturers would not dare to recommence manufacture with the menace of the unfair German practice still existing as a possibility. The danger of Germany resuming practices of this kind is considered very real by many chemical manufacturers. How real this danger is we have no means of definitely determining.

Before the war international trade was essentially anarchistic; that is to say, each nation controlled, as it thought best, all questions relating to export and import; everything was permissible under international law. Import taxes could be raised or lowered by any nation as it saw fit. Each nation could lay down its own rules for import admissions. The nearest thing to a general rule which would remove international trade from the anarchistic class was such provisions in treaties in what are known as the most favored nation clauses. These clauses prevented any nation from discriminating against another nation protected by such a treaty in the matter of import or export restrictions.

Germany's Abuse of Freedom of Trade

Under these conditions, as has been stated, everything was permissible, and Germany was best known among the nations of the world for its aggressive abuse of this freedom in international trade. It has been claimed even, that if a manufacturer in another country attempted to follow the same practices as Germany followed, and shipped goods to Germany for the purpose of selling them in the German market at the market price or perhaps below it, he ran the danger that some quickly executed decree would prevent the entry of his goods into Germany, perhaps just at the moment when they had arrived at the German port of entry. An attempt by an individual manufacturer to break down this vicious German practice would, if successful, inure not to his benefit only, but would inure to the benefit of the other manufacturers in his own country and throughout the world. Partly to meet this situation, what was known as the Webb law was passed by our Congress, which permits manufacturers to combine for export business. This law was passed, however, too late to be of much use to American chemical manufacturers, as the war had started. As we are considering the problems now, and not presenting the solution, we will consider the Webb law further on when we are talking of this solution.

The danger of Germany becoming an acute and disturbing factor in international trade is increased by the prospect that Germany will be compelled to incur heavy bonded indebtedness held by foreign nations and their peoples. If Germany should largely become a debtor nation, she can only pay the interest on her debts by an excess of exports over her imports. The heavier the burden laid upon Germany in this respect, the more certain Germany is to become a competitor in the world's markets. Her gold will be drained from her and as soon as that draining has reached its practical limit, the only thing that she can then pay with will be the products of her labor. As she will need all she can earn to pay her taxes and indemnities and as these will increase her production costs, she may not be able to sell at prices that are menacingly low.

A Future Economic Problem

Couple with this the fact that during the war the United States has become a creditor nation and its credits and the interest upon them can only be paid, to a certain extent, in gold, of which apparently we have more than is good for us at the present time, and the remainder in merchandise, it can readily be seen that we are in danger of having goods offered to us at relatively low figures, not only by Germany but all other countries, these goods consisting at least to some extent of chemical products.

In order to give a true picture, however, of the situation, we must not neglect to look at the other side. German chemical industries, except for war purposes, have been almost at a standstill for over four years. Many of her plants must have passed into a condition of innocuous desuetude. Each of us knows what it means for a plant to be practically idle for four years. The plant itself deteriorates and the men on whom the successful operation of the plant has depended have become scattered, in many cases have died, and in all other cases, to a certain extent, have lost their art. It is hardly probable that the German chemical industries (speaking now with reference to peace products) are in anything like the good shape in which they were before the war. Furthermore, it seems probable that chemical research along peace lines must have almost ceased in Germany. In this country the reverse of all of this is the case. Our chemical industries have received a tremendous impetus. Men have become trained in chemical operations. Extensive chemical research has been going on in connection with peace manufacture.

Germany an Ishmaelite

There is another phase of this situation, too, that must be considered. Germany has become the Ishmaelite or the pariah of nations. Practically the whole world is wrought up with an intensity of feeling that will prevent the sale of her products if known to be of German origin. Think of this picture as portrayed by James Church Alvord in the New York *Times*:

> By rotting wharves her empty ships shall rock,
> Her shattern towns their poverty proclaim,
> Her high-towered factories topple block by block
> "Since "Made in Germany" is a brand of shame.
> Thrust from the door of Human Brotherhood,
> Misunderstanding and misunderstood,
> Beggared, unpardoned, excommunicate—
> The Ishmaelite shall wait.

If the picture is a true one, can we really have very much to fear from serious competition with Germany? If true, it indicates that Germany has beggared herself morally and physically, that about the only thing a German can do is to leave his native country, change his name and try to rehabilitate himself in other climes. Mind you, this picture is not one that I am painting, and I do not present it as a picture originating in my mind, but I do present it as a picture that is in the minds of a very large percentage of civilized peoples.

Assuming the very worst as to the dangers of German competition, what is the best method of procedure, utilizing implements at hand, for meeting such competition? I offer three practical solutions. The first of these is a combination of the chemical industries for export trade purposes, under the so-called Webb law; second, the formation, in the chemical industries, of what are known as Open Price Associations; and, third, the combination of chemical concerns which are not competitive and which are too weak to stand alone—by combining they would be strong.

Webb Law

This law, which went into effect April 10, 1918, has for its purpose the granting of permission to domestic manufacturers, sales agents, etc., to combine for the purpose of fixing prices and controlling export trade in the industries in which they are interested. The act starts off to define what is meant by export trade, which means solely trade or commerce in goods, wares or merchandise exported or in the course of being exported from the United States or any territory thereof to a foreign nation. The act is presumed to relate to trade outside of the United States or any of its possessions, such as Porto Rico, the Philippines, etc. In the act the word "association" is used, which is declared to mean "any corporation or combination, by contract or otherwise, of two or more persons, partnerships, or corporations." Evidently it permits a pooling of export profits, which is not permissible in domestic trade to the extent that it interferes with competition. To accomplish its purpose, the act simply declares that previous acts, including the so-called Sherman law, shall not be construed to apply to associations entered into for the sole purpose of engaging in export trade and actually engaged solely in such trade, provided such association does not "enter into any agreement, understanding, or conspiracy, or do any act which artificially or intentionally affects prices, in the United States, of the commodities of the class exported by the association, or which substantially, in the United States, or otherwise restrains trade therein." It also provides that the act creating a federal trade commission which defines and prohibits unfair methods of competition shall not be construed as to apply to competition in the export trade. It also calls for the filing with the Federal Trade Commission full details as to the association formed under the act, and penalties for failure to make proper reports. It also gives to the Federal Trade Commission power to initiate prosecution of associations that do not operate within the limitations of the act.

Aim of the Act

This act apparently will permit manufacturers, etc., to form associations that can do practically anything in export trade, so long as their acts do not restrain domestic trade or affect competition therein. It would appear that these associations could do things in export trade that would be considered unfair in domestic trade. Thus if any foreign country attempts to dump its goods on this country for the purpose of injuring domestic trade, the export association could retaliate by selling abroad its products, even at a loss, in order to prevent such dumping.

It is possible, however, that this phase of the act may be subject to the qualifications that the association's export sales are distinctly for the purpose of building up foreign trade and not for the purpose of interfering with domestic competition. However, an act of this kind will have to be interpreted as its practical applications develop. One thing is clear, however, that if associations are formed under this act before foreign goods can be dumped upon this market, and if these associations aggressively seek to develop our export trade in products which might be dumped upon our market, no criticism could be made, as it could not be shown that they had directly affected competition in this country or restrained domestic trade.

I do not know that I have made my point clear. Let me illustrate it. Suppose there is a certain product which our domestic manufacturers fear may be dumped upon our market. Manufacturers who are engaged in the production of this product can form an export association. If this association is formed in time and endeavors to develop foreign trade in this product before the same product made abroad can be imported, their act cannot be considered in any way illegal. It would also appear that they can continue to offer this product abroad on the same basis of price, etc., even after the foreign-made product was offered in this country. If, however, the association was not formed or did not commence to act until the foreign product had already been dumped upon this market, thereby depressing domestic prices, and they should then go into the foreign market for the purpose of preventing such importation, with the result that domestic prices would be increased, the association might be doing an illegal act. I am only attempting to give a common-sense view of this phase of the subject and it may be that my opinion is subject to revision by the mind legally trained. Also it would be manifestly foolish for me to give advice as to what should be attempted under this law in any particular case. Each case should be judged of by itself.

Pooling of Selling Interests

The main purpose of the act is undoubtedly to provide for collective bargaining in the export business. By collective bargaining is meant the pooling of selling interests so that those in the pool will not be bidding against each other, thereby depressing prices.

It is interesting to note that a number of associations have already been formed under the Webb law. Very few associations have so far been formed covering the chemical industries. It is presumed, also, that most of the associations so far formed have been for the purpose of providing collective selling, as in the case of the recent associations covering copper and steel, formed under the names of the Copper Export Association and the North American Steel Products Corporation. No one can tell to what extent the utilization of the Webb law will assist chemical industries. It certainly should, however, be studied by our chemical industries, both from the business and legal standpoint, so as to see how profitable use can be made of it. It would appear to be a very efficient instrument for the development of export trade and the meeting of foreign competition.

During the last few years a great many Open Price

Associations have been organized. Some few of them have been formed covering certain branches of chemical manufacture. Open Price Associations have for their purpose the bringing together of manufacturers of competing products, for the purpose of establishing trade practices and for the general welfare of the trade, to encourage a spirit of good will and mutual confidence among their members and with the trade, to co-operate with each other and with the Government authorities, to prevent unfair methods of competition and trade abuses, to study and adopt ways and means of eliminating waste in production and distribution, to establish and maintain standards as to quality and to induce truthful branding of products, to study manufacturing costs, devise scientific methods of accounting, and to furnish the members with useful information. All of these things an Open Price Association can do if it determinedly avoids anything like a reduction in competition or attempts to control prices. Apparently Open Price Associations have met with the approval of the Federal Trade Commission. One of the great evils they seek to correct is what may be described as the sporadic cutting of prices, due to misinformation as to what competitors' prices are. Thus, John Jones hears through the trade that James Smith is after a certain line of business and has quoted very low figures. In a great many cases the information which has come to John Jones is false and is not, under ordinary conditions, subject to verification. He simply has to guess as to what James Smith is doing, and, being fearful that James Smith may beat in the race, he becomes nervous and cuts his price to a figure in which there may be no profit or even a loss. Such a condition is ruinous to business; it serves no good purpose and is in the nature of unfair competition. If, however, there were some system provided whereby John Jones would know in due time exactly what James Smith was quoting, or vice versa, neither of them would be willing to go on record in making ridiculous quotations.

Two Methods of Procedure

This indicates the essential feature of Open Price Associations. To accomplish its purpose two general methods of procedure may be followed. One method is that each member of the association reports to its secretary all sales, the secretary in turn reporting these sales to all of the other members of the association. The other method of procedure is this: If all members published their price lists, they would then report to the secretary only deviations from the price list, the secretary then advising all the members of such deviations. The second method is one most easily followed with staple products.

Of course it is obvious that no Open Price Association of the kind described can exist unless the members of the association have a certain degree of confidence in each other. The simple reporting of prices or deviations from price lists will not accomplish much unless the members are honest in their reports. In other words, it is the spirit which develops out of such an organization that is its real value, the spirit of confidence. I presume that in the formation of these organizations, in some cases, the members have come together with the fear and trepidation which Ali Baba felt when he entered the cave of the forty thieves. After an organization of this kind has been in existence for a while, however, each one begins to be ashamed of himself for having thought so poorly of his competitors and he finds that after all he has no monopoly on honesty and that the other members of the association are not very much better or very much worse than he is. As time goes on he also finds that they are a great deal better than he ever thought it possible for them to be.

Right Spirit Must Prevail

The Open Price Association is not a cure-all, and unless entered into with the right spirit it undoubtedly could become a menace. The great temptation for the members of an association is to think that they are gathered together for the purpose of controlling or regulating prices, which of course is illegal. Those that appreciate this danger will studiously avoid any attempt at the control of prices. The association should not eliminate competition; it should not attempt to say what any member shall do with respect to prices. So far as I know, no Open Price Association has as yet been accused of attempting to regulate prices. Some time such an accusation may be made, but if so, every other association will, for its own safety, more strenuously stay safely within the legal line.

I urge upon the chemical industries the study of this proposition. I believe wherever an Open Price Association is established among chemical manufacturers the result will be better trade conditions, more uniform and more legitimate profits and a greater respect on the part of the consuming public. The cutting of prices below what will give a legitimate profit is not good for the consumer because in the long run what the consumer needs is stability in prices that are sufficiently low. He should not want an unfair advantage in the purchasing of goods, nor should he want a manufacturer to supply him with goods on which a reasonable profit has not been made.

Some Open Price Associations have considered the possibility of using their associations in the furtherance of export business. This is a legitimate development of the Open Price Association, although better conducted in associations formed under the Webb law. Whatever they may do in this respect, however, it is certain that in Open Price Associations there is an opportunity presented for the discussion of foreign competition. They can act collectively within certain broad limits to cope with this competition. They can conduct an advertising campaign in favor of domestic products. They can furnish each other with information which will enable them to manufacture more cheaply and so be able more easily to meet foreign competition.

The chemical concern that manufactures only one product, or only a few products, is at a great disadvantage as compared to a concern that manufactures a great many products. The uses of chemical products come and go, the demand for them rises and falls, new chemical products are discovered which are continually displacing those previously manufactured. The profits of a concern manufacturing one product, on being plotted, will show as a rule a very irregular curve. There may be frequent rises and falls; there may be a very rapid rise and then a very rapid fall. I think

if any large chemical manufacturing company had the information at hand and could plot its profits with regard to individual products, it would be found that these curves would be very irregular and, on the other hand, that if they were all combined, other things being equal, there would be shown a more nearly continuous and uniform curve that, with a well-managed concern, would steadily rise.

Widen the Base of Business

I am therefore laying down the rather fundamental proposition that concerns manufacturing chemicals should have as wide a base as possible in order to maintain their stability. I am probably offering nothing new in this suggestion; most chemical companies see the point involved and they have diversified their industries so that loss in one department will be corrected by profits in others. I am wondering if it is not true, however, that during our war period many concerns have gone into the manufacture of specialties without a broad enough base to give them permanence. Is not it possible that there are chemical manufacturing companies in this country that are on too small a base, but which, if combined with some other industry in a similar condition but manufacturing different products, would be able to weather the storm of competition? I am wondering if we have sufficiently learned our lesson from Germany in the diversification of our chemical industries. Are our manufacturing chemical concerns each as inclusive as the German companies in the number of products that they manufacture? Here is a path of progress that I am sure leads to profit.

Combines Suggested

It would be foolish, however, for a concern that is manufacturing one or a few products, to think that the only way for him to diversify his industry would be by increasing the number of products. Probably the best thing for it to do would be to combine with some other concern similarly situated but manufacturing other products. As I see it, there is nothing illegal in such a combination, as they were not competing. Of course, to a certain extent, even competing industries can combine, so long as the combination is clearly not one in restraint of trade, and the mere fact that some of the products of one of these companies are manufactured by the other company is no reason in itself why the two companies should not combine, unless by so doing they obtain a monopoly of product. I am not advocating such a combination. The combination I do advocate is only one which will result in the broadening of the base and the diversification of the industry. In many cases the by-products of one of the companies could be utilized in the manufacturing of the products of the other company, the economy thus resulting being a benefit to both and to the public at large.

If a chemical concern cannot hold its own in domestic competition, how can it hope to meet foreign competition as well? If it rests on a narrow base, how much more likely it will be to topple over in the struggle of foreign competition. By broadening its base it can withstand competition both domestic and foreign.

The danger of our chemical industries being injuriously affected by foreign competition would be very much lessened and in some cases would be entirely removed if our chemical industries made use of the three instruments I have outlined, to wit: Association for export business, under the Webb law; second, the formation of Open Price Associations; and, third, the diversification of industrial operations by such combinations as are possible without destroying competition. Individual initiative would remain intact in the case of all of these instruments and would not involve the asking for Government assistance.

Destructive Domestic Competition

Asserting that the elimination of domestic competition, so far as it is destructive to industry, can only be brought about by combinations which to a greater or less degree restrain trade, there are those who advocate the repeal of the Sherman law so as to permit combinations in restraint of trade. Personally I am opposed to any advocacy of the repeal of the Sherman law, primarily because I do not believe that it is a menace or that its repeal is necessary. Particularly is this true with regard to our chemical industries. I have already indicated how, to a certain extent at least, the evils of old-fashioned competition can be eliminated by Open Price Associations, and I have also indicated that the real need of our chemical industries is diversification through combinations that are not in restraint of trade. My principal objection to doing away with the Sherman law, outside of the fact that you could not get it repealed if you wanted to, lies in the proposition that nearly all progress is traceable to competition. If you destroy competition, you destroy individual initiative, which is the thing that above all other things should be developed. Forms of organization which appear to be logically complete but which after all substitute autocratic and bureaucratic methods for individual activity have in them the seeds of their own destruction.

To meet destructive domestic competition, all I have to suggest is the formation of Open Price Associations and the diversification of industries through combinations that are not in restraint of trade.

Falling Prices

One of the most serious things that appear to confront us today is high prices. If we knew that the present prices were to be maintained, that they would not drop back toward what they were before the war, we would have very little concern. We all know that there will be some falling off in prices, because war demands took up such a large supply of goods and labor as to force prices above their natural level. We may, however, be surprised and prices may not go back to their former level. Economists tell us that in general prices, after the Civil War, did not go to the level of what they were before the Civil War, and I venture to express the opinion that not for a very long time, if ever, will prices in general go back to the level they were before this world war. It would lead me too far to go into a discussion of the money question. The quantitative theory of money is pretty well established, and this theory teaches us that prices vary more or less directly with the per capita volume of circulating medium and whatever this circulating medium rests

upon. It is probable that the high prices in the United States are directly traceable, to a large extent, to the issue of Government bonds. These Government bonds are in the nature of extensions of credit, and extensions of credit are equivalent to an increase in the circulating medium. Germany has issued large quantities of paper money, and our associates in this great war have to some extent done the same. The Government bonds of our allies and our own country will form a basis of credit which, as I have said, is an increase of the circulating medium. High-priced labor means high prices for goods. If for no other reason, the resistance of labor to a reduction in wages will prevent, at least to some extent, a fall in prices.

For all these reasons I do not believe that the losses due to falling prices are going to be as great as some of us imagine. Of course the conservative business man has already taken care of this possibility, to a certain extent, by writing all of his inventories at low figures. How far he has been allowed to do this by the Treasury Department I am unable to say, but my understanding is that whether the Treasury Department would allow him to do this or not, in figuring his profits, it has allowed him to create such reserves as may be necessary to meet this condition. If reserves have not been created and profits have been divided on full war earnings, he is apt to be in a bad way and I know of no means of saving him without what would correspond to a surgical operation. If possible, reserves should be created in order to meet the possibility of lower prices.

High Wages

As I have already indicated, I do not feel that prices will fall very much or that wages will be very much lower. I am not considering here what we would want to do or what labor leaders want to do; I am only presenting my own diagnosis of the situation. If, however, wages do tend to go down, there will be something of a corresponding fall in prices. Each employer will have to consider the extent to which it is profitable to him to reduce his employees' wages. He has very little arbitrary power in this matter, but he can exercise a considerable amount of intelligence, and I personally believe that high-priced labor is more profitable than so-called cheap labor, although I do not mean by that that if you increase an employee's wages you thereby immediately increase his efficiency to a greater extent. I notice, however, that the men who are getting the highest wages usually get them because they are worth more than those who are getting less.

There will be a feeling of duty on the part of every employer of labor to take back those employees who have been in the Government service, finding positions for them as best they may. Many of these men who have served in the Army and Navy will come back with increased efficiency, unless indeed that efficiency is interfered with by injuries received. They will have a new view of life; they will be more democratic in their valuation of men than they were before. I am inclined to think that the men and women who have been in the service will have ideas that the intelligent employer cannot ignore. They will have become a political force of no small magnitude. Many of them have been fed by Uncle Sam better than they were ever fed before. In general their standards of living will have risen. The intelligent employer will not see his way clear arbitrarily to reduce wages. In view of these facts, the unintelligent employer, if he attempts to exercise his arbitrary power, will be confronted by strikes, without the support of public sentiment.

I do not know how to meet this problem of the wages of labor, except through a broad sympathetic spirit that says, "I may have to reduce wages and if I have to I suppose I shall, but as long as it is in my power not to do so, I will not do it."

I make this suggestion simply as a business proposition. There are enough things confronting us to disturb business conditions and we should not seek for other forms of trouble. Undoubtedly there have been a great many employees discharged, with more to follow. There will be a large number of possible employees released from the Army. There will be a freer labor market. But many of our industries have been very short of labor for a long time and this shortage has not been met as yet. There may be no surplus of labor. The demands of the world for labor's products show no abatement. With peace production so much curtailed and with the awful destruction of wealth during the last four years, it would appear that the demand for industrial products would be great for some years to come.

Organization of Chemical Industries

I have already indicated how, under the Webb law and through Open Price Associations, our chemical industries can become more highly organized. There is little I have to suggest beyond this. I have only this thought to add. I know of no industry that is so continuously changing as the chemical industry. It cannot stand still. It must either go forward or backward. To go forward there must be co-operation between our industries and our educational institutions, there must be more chemical research and more active drafting of men of technical education into the commercial world.

In conclusion let me add this further suggestion. Opportunities very seldom come knocking at our doors. They are usually met in the course of our search for definite things. The recognition of opportunity when one meets it is a measure of intelligence. Particularly is this true in chemical industries. Opportunity presents itself in the unexpected discovery of new products and in the unexpected discovery of new uses for relatively old products. Very often opportunity appears at first in the disguise of failure. In general the success of any business, or we might say everything, depends upon its opportunities, but it also depends upon their utilization.

What the future holds in store for us is largely a matter of opinion and my opinion makes me an optimist. I am optimistic as to the opportunities that lie before our chemical industries. I am optimistic that our chemical industries are managed by men of so high intelligence that the opportunities that lie before them will not be overlooked. The world is in a state of flux requiring the greatest agility of mind if legitimate profits are to be extracted. This agility of mind I believe we possess. The future can only determine whether I am right or wrong.

Being a Journey of Observation in England, Scotland, Belgium and France With a Party of Editors of American Technical and Business Papers, at the Invitation of the British Government

ONE of the Great War's products in the United States was a fine spirit of co-operation and helpfulness between the Government and the technical and business press of the country; in fact, the relationship became so intimate and satisfactory that the press was looked upon as one of the strong arms of the Government in accomplishing its purposes. It remained, however, for Great Britain, through its Ministry of Information, to crown this local recognition of the business press by inviting a party of fifteen editors and publishers of technical and business papers of the United States to visit England and France in order that civilian intercourse among those nations might continue in spite of the obstacles interposed by military regulations. The following representatives comprised the party:

Horace M. Swetland, President United Publishers' Corporation, New York.

Arthur J. Baldwin, Vice-President McGraw-Hill Co., New York.

H. C. Parmelee, Editor CHEMICAL AND METALLURGICAL ENGINEERING, New York.

Henry G. Lord, President *Textile World Journal*, New York.

Roger W. Allen, President New York Business Publishers' Association, Inc. *American Hatter, Millinery Trade Review*, and *Nugent's—The Garment Weekly*, New York.

David Beecroft, Directing Editor of the Class Journal Co., New York.

H. L. Aldrich, Publisher *Marine Engineering* and *The Boiler Maker*, New York.

Samuel O. Dunn, Editor *Railway Age*, Chicago.

William W. Macon, Managing Editor *The Iron Age*, New York.

Floyd W. Parsons, Editor *Coal Age*, New York.

H. E. Taylor, Business Manager *Dry Goods Economist*, New York.

Frederick F. Cutler, President *Shoe and Leather Reporter*, Boston.

H. Cole Estep, Editorial Director Penton Publishing Co., Cleveland.

Edw. H. Darville, *Hardware Age*, New York.

Sailing from New York on the S. S. *Lapland*, Oct. 26, 1918. we left the United States under all the conditions of secrecy imposed by military regulations. Our ship carried about 2500 troops, a contingent of the Army Nurse Corps, some British officers who had been assisting in the campaign for the fourth Liberty Loan, and a small group of civilians. About 4 o'clock in the afternoon we dropped down the river to the lower bay, where we joined a number of other ships, all camouflaged like our own, and anchored for the night. The following morning we were joined by still other ships, and about noon the great *Leviathan* steamed past us, loaded with thousands of troops. During the rest of the day we were treated to the impressive and spectacular sight of a great fleet of between 50 and 60 vessels starting across the ocean with troops, munitions and supplies, as part of the great answer America was making to the Kaiser's sneering taunt that we wouldn't fight.

DESPATCHING A FLEET TO EUROPE

The precautions for safety taken in despatching that great fleet to sea were a matter of astonishment to all. Hydroplanes, submarine patrol boats, captive balloons, a dirigible and several destroyers paid incessant attention to the departing vessels. The air and water were filled with these small craft scurrying here and there, guarding against any surprise attack from a lurking enemy. For several hours we were thus attended as we put to sea; and all this was accompanied by incessant signaling from ship to ship, by semaphores, pennants, wigwagging and flashing lights. Long before dark the

THE AMERICAN EDITORS IN HOLYROOD PALACE, EDINBURGH

fast *Leviathan* had disappeared over the horizon, and the balance of the fleet had spread out in fan shape extending as far as the eye could reach. One could be pardoned a thrill of pride in this evidence of the extent to which our great war machine was working in conjunction with the Allies.

During the night the great fleet must have separated into smaller groups of vessels, because the next morning we were in a small fleet of 14 troopships and freighters, convoyed by a United States cruiser and a destroyer. The fleet was formed roughly in column of fours, with the cruiser leading and the destroyer in the rear. Our course was changed a few degrees about every seven minutes, and thus we zigzagged our way across the ocean.

The rules and regulations for passengers were evidence of the unusual conditions surrounding our voyage. Life jackets were either worn or kept in hand at all times; we were not allowed in the dining room without them, and they were in evidence at card games in the social room or at divine service on Sundays. No lights or smoking was permitted on deck after sundown, and no passengers were allowed on deck after 10 o'clock at night. Guards were posted throughout the ship as in a military camp; submarine lookouts were stationed at points of vantage; guns were mounted fore and aft, and depth-bomb guns on either side of the ship. The life-boats were swung out of their davits ready to be lowered instantly, and rope ladders were provided at frequent intervals along the deck for use in case it became necessary to abandon ship. Numerous life-rafts and collapsible boats were placed on the upper deck, all provided with fresh water and provisions. All troops and civilian passengers were assigned to numbered life-boats, and a drill was held twice daily to familiarize us with the procedure in case of accident. The civilian accustomed to ocean travel in peace times would not recognize his surroundings or comprehend readily the habits and customs of the ship's company.

The voyage was without any spectacular incident due

CHATEAU RADINGHEM, HEADQUARTERS FOR VISITORS

LOOT FROM THE CATHEDRAL IN DOUAI

A SILHOUETTE AT YPRES

to the menacing submarine. On one occasion a ship dropped out of our fleet, due to trouble of some kind, and disappeared over the horizon to the rear, attended by the destroyer. On the following morning both were in their accustomed places. At another time, when we were approaching the Irish coast, our course was abruptly changed 180 degrees for an hour or more, when we resumed the original course. Naturally there was never an intimation as to reason for these things and we remained in ignorance of their cause or purpose. As a matter of fact, we know now that the submarine menace had been practically eliminated at that time. The convoy system and the depth bomb had rendered the submarine of no avail against their most important targets—troopships and freighters. Credit for both these ideas is to be given to Admiral Jellicoe of the British Navy, whose resourcefulness and ability in devising these means of defense were publicly acknowledged by our Admiral Sims at a dinner given in our honor in London.

Convoyed by British Destroyers

Approaching the Irish coast and the recognized danger zone, renewed precautions were taken for our safety. Troops were brought out of the hold and made to sleep on deck. Our own cruiser and destroyer turned back and left us, and we were picked up by eight British destroyers that convoyed us to Liverpool. The sea was heavy and these light small craft bobbed about like corks; and one was impressed with the discomfort that must attend life on such boats. In fact it began to dawn on our minds that the sailors navigating the coast patrols, mine sweepers, destroyers and merchant vessels have played a part in this war that will not be generally appreciated. Someone who knows should write the story of these heroes, their constant devotion to duty under the most uncomfortable and dangerous conditions, and their refusal to be intimidated or deterred from returning to sea even after they had been torpedoed one or more times. About 5000 small craft have been engaged in this work of coast patrol, mine sweeping and convoying, cruising at times a total of 6,000,000 miles in a single month, and providing throughout the war for the safe carriage from all ports and in all directions of a total of 15,000,000 men.

We landed at Liverpool on Nov. 8, after a voyage of 13 days. Here we were met by military representatives of the Ministry of Information, Col. E. L'E. Malone and Major George Whitmore. The latter was to be our guide, mentor and friend for six weeks, making easy our path through England, Scotland, Belgium and France; attending to passports, hotel accommodations, railroad tickets, taxis, etc., and securing for us many courtesies wherever we went. As a result of his

PUBLIC SQUARE IN ARRAS

REPAIRING THE MENIN ROAD, BELGIUM

MARKING THE SITE OF A DESTROYED VILLAGE

efforts we escaped many of the difficulties of travel during war times, as well as the necessity of reporting to the police on arrival at and departure from a city. Hotel registration, however, he could not relieve us from, and it was always necessary to give our intimate personal and family history at each new hostelry.

Conditions in London

At Liverpool we were provided with a special car on the London & Northwestern and went directly to London, arriving there about 10 o'clock at night. Here we encountered new precautions for safety from German attack—this time from the air. London was dark. An occasional street lamp was lit but masked with paint, and taxis carried only a dim light. Illuminated red signs at frequent intervals along the street conveyed the cheerful information that "air raid shelter" could be found in some adjoining basement or subway station. The first sight that met my eyes when I looked from the hotel window on the following morning was an immense captive balloon, suggestive of the constant patrol of the air that had been maintained since air raids on defenseless cities first were instituted by the enemy.

London was also cold, partly because of a shortage of coal and partly because the central heating plant for large buildings is almost an unknown quantity. The wasteful and inefficient open fire-place still holds sway in hotels and office buildings. Poor enough in ordinary times when there is plenty of coal, this system becomes intolerable when fuel is strictly rationed. The experience should bring home to England the necessity for burning her fuel more economically and at the same time getting some satisfaction out of it.

It cannot be said that London was hungry, but food was strictly rationed. There was enough to eat and the food was good. It lacked variety and "frills." Fruit was scarce and expensive. Sugar was issued only on delivery of the proper coupon, and we carried a week's supply of lump sugar in our pockets. Meat also was served only on presentation of the ration card, from which the waiter clipped the necessary coupons, and if the week's allotment were used at one meal, no more was to be had the balance of the week. On every hand was the evidence that London's sole business and concern was the war and its successful conclusion. These were the conditions under which the city had pursued its war vocations for four long years, never doubting the ultimate triumph and asking only time enough to train men and produce munitions. I could not help being impressed with the fact that despite the tremendous effort America was making and the vital contribution she was offering to the winning of the war, nevertheless our people had not begun to understand what sacrifice meant. Our resources were of such extent that we met the demands on our time, ability and money almost without self-denial and certainly without great sacrifice. England, on the other hand, had paid a price that we in America could not comprehend without closer contact with the British people.

The Lord Mayor's Show and Armistice Day

The day following our arrival in London was the occasion of the Lord Mayor's Show, or inaugural parade. This is an ancient ceremonial, participated in by the different guilds or associations of artisans and workmen and the representatives of the city government. A decided military aspect was lent to the parade in 1918, every branch of the British forces being represented. Allied troops also participated, and it was noticeable that the company of United States infantry received greater applause as it marched along the route than did any other unit. This demonstration, we discovered later, was a fair indication of the esteem in which America and her troops were held by England. There was the deepest appreciation of our co-operation and assistance, and an expressed feeling that the splendid relations that had grown out of the war would continue to animate the two nations in their future dealings with each other, as well as in their efforts to solve world problems.

Within three days of our arrival in London armistice was declared, an event which was jocularly referred to as additional evidence of the power of the business press of America. Either Paris, London or New York would have been wonderful places in which to observe the celebration of the armistice, but I shall always be glad that I saw it in London. The city gave itself over to the most unrestrained rejoicing. At 11 o'clock on that eventful day the explosion of the maroons announced the glad news. Within five minutes I was in the Strand, thrilled at the sight. Women, old and young,

ROAD IN FLANDERS

married and unmarried, swarmed into the street from the buildings in which they were working. With tears streaming down their faces, which at the same time were broken into smiles, they paraded, danced, sang and cheered. Not one of them but had felt the sting of war or the loss of some male member of their families, and the pent-up emotion of four long years was not to be restrained on receipt of the good news of the end of hostilities. The crowds gathered until traffic was impossible. A band of Scotch pipers appeared, followed by a long line of paraders. People rode on the hoods and fenders of the buses and taxis, and commandeered trucks and automobiles. Flags and colors appeared in such profusion that the city soon wore a holiday appearance.

A TRENCH IN FLANDERS

Business was suspended and the crowds of merrymakers owned the town. The London "bobby," wise in his day, stood aside and let the crowd have its way, well knowing that the celebration would be orderly. As a matter of fact, the only disorder of the week was the burning of some captured German artillery which was hauled to Trafalgar Square and made into a huge bonfire.

England's Reception to the Technical Press

Our first week in England might be described as reception week. The Ministry of Information had made elaborate arrangements for the business editors of the United States to meet and become acquainted with the leaders of British thought and opinion. Many of these meetings were arranged under the most delightful circumstances, such as the dinner and afternoon at the country place of the Duke of Sutherland near Guildford. Here were assembled a group of English men and women who were engaged in war work of various kinds, as members of Parliament, officers in the Army—workers in hospitals, inns for officers on leave, etc. The conversation turned to intimate phases of life and war work in the two countries and gave each an opportunity to understand better than ever before just what was in the heart and purpose of each nation and how each was trying to accomplish the desired end.

A formal luncheon by the Ministry of Information came by chance on Armistice Day, which gave a new aspect to our reception. Other luncheons and dinners followed in rapid succession: by the English-Speaking Union, the British Newspaper Conference, Sir George Perley, Lord Burnham, the National Trade Press, General Smuts and the American Chamber of Commerce in London. These were attended by eminent statesmen and representatives of industry in Great Britain, and their utterances on those occasions were reported in full in the daily press of London.

The English-Speaking Union is an organization the purpose of which is sufficiently indicated by its name. With the Rt. Hon. Arthur J. Balfour as its president, it is composed of the leading thinkers of Great Britain who are desirous of bringing about a closer relation between the English-speaking peoples of the world. At our luncheon Sir Arthur Steel-Maitland presided, and we were addressed by Mr. John Hodge, Minister of Pensions, and Major Evelyn Wrench. Others in attendance were Sir Gilbert Parker, Lord Desborough, Sir Campbell Stuart and American Consul General Skinner. Cables of congratulation were despatched by the Union that day to Marshal Foch, Field Marshal Haig, Admiral Wemyss and General Pershing.

At the dinner of the British Newspaper Conference the principal speakers were Mr. Balfour and our own Admiral Sims. The dinner by Lord Burnham, owner of the London *Telegraph*, was a brilliant function at Claridge's, attended by Winston Churchill, Sir Frederick Smith, Sir Arthur Pearson, the Lord Mayor of London and some of the other city officials, Raemakers the cartoonist and other notable people. It was on this occasion that Sir Frederick Smith told of the desperate situation in France in the spring of 1918, when plans were made to salvage whatever was possible of the British forces and supplies in France and begin preparations for a still longer war before victory should be won. At no time was there a thought of defeat, but only terrible and costly delay in the final accomplishment. The British fleet was always the strong reserve arm of the empire, and could be relied upon to protect the homeland and keep the seas open until men and supplies could again be marshalled in sufficient numbers to gain the victory. Winston Churchill spoke feelingly of America's aid in the war, characterizing our intervention as "the greatest mental effort and spiritual realization of truth which has occurred in the whole course of secular history."

Mr. Churchill on British Sea Power

Mr. Churchill spoke again at the luncheon of the National Trade Press, and paid his respects to those who deprecate British supremacy of the seas. Sea power is vital to England and her colonial possessions, he said, and could not be minimized without jeopardizing the integrity of the empire. With regard to future military and naval preparations by the nations of the world, Mr. Churchill proposed an international register of all naval, aërial and military plans, and an international commission of inspection to see that no secret preparations are made.

One of the most interesting and important functions was the dinner given by Lt. Gen. J. T. Smuts, a Boer who had fought Great Britain in South Africa in the Boer war, but who was now in the British forces and a member of the Supreme War Council of five. Gen. Smuts had cleaned up German East Africa before coming to London, and had shown his loyalty to the principles of Great Britain despite his "slight difference with

that country some years ago." In the course of a statesmanlike speech, he paid tribute to the beneficent régime which Britain has always endeavored to establish in her colonies and over conquered peoples. One could but contrast the attitude of those peoples who have been conquered by the Germans during the past four years. Admiral Jellicoe, Arnold Bennett, Lord Islington and other distinguished gentlemen attended this dinner.

Despite the appearance of a round of social pleasures which this succession of functions suggests, there was a serious purpose in all of it, and the luncheons and dinners were merely the medium chosen for its accomplishment. It was a tribute to the technical and business press of America of which we may well be proud.

St. Dunstans, a School for Blind Soldiers

During this first week we found time also to visit St. Dunstans, a school for blind soldiers; the Y. M. C. A., Eagle hut and officers' inns, and other places of interest. St. Dunstans holds unusual interest because it is making independent, self-sustaining, useful men out of blinded soldiers. The grounds and buildings were loaned for the purpose by Mr. Otto Kahn of New York, and the organization of the teaching force, etc., was arranged by Sir Arthur Pearson, himself blind for the past few years. The psychology of the institution as presented to a blinded soldier just entering may be expressed about as follows: "You are not blind and therefore helpless; you have merely lost one of your five senses, and you still have four that you know little or nothing about. They can be trained so that you can be an independent and useful member of society." A story of wonderful human interest could be written about this institution, which practically embodies the common sense of an intelligent man who knew that it was possible for a man to lose his sight and yet preserve his independence.

A Visit to the Grand Fleet

The Grand Fleet of the British Navy is a powerful agent for peace or war. In years past it has been both, no doubt, but during the last four years especially it has been the greatest silent potential force of the Allies in their struggle against German world domination. Knowing something of the majesty of this arm of the British defense, we were delighted to have an opportunity to visit the fleet. Our course lay by rail to Edinburgh, and thence by motor to Rosyth, where the fleet lay in the Firth of Forth. Fog prevented our getting a view of the entire fleet at one time, but we rode in a motor launch up and down the lines of dreadnoughts, battleships and cruisers, all lying at anchor inside the famous Forth bridge. A few battleships of the American squadron were lying just outside the bridge. We were received on board the *Orion* by Admiral Goodenough and the ship's officers, and subsequently divided into parties for dinner on several of the battleships, the party of which I was a member going to the *Monarch*, where Capt. Drury-Lowe and his staff received us most cordially. After dinner we inspected the ship from fighting-top to engine room, and observed in action the mechanism for loading and firing the big guns in the turrets. Returning to the *Orion* we were all taken to the *New Zealand*, and after a brief inspection and reception we returned to shore.

CATHEDRAL AT ARRAS

Our visit was just two days prior to the surrender of the German fleet, and the British officers were anticipating the event with mingled feelings of satisfaction and regret. They would much rather have sunk the enemy in a fair engagement, and considering their four long years of vigilant watch, one could not deny them the wish that they might have met their enemy in an open fight. I think they still hoped, and maybe suspected, that the enemy would not surrender without a show of force, but they were all ready to meet him.

The Lord Provost and Corporation of Edinburgh tendered us a dinner at the City Chambers, where we met the leading men of the city. Arrangements were made for a special visit to the famous Castle, under command of Sir Robert Moncrieffe, and to all the apartments in Holyrood Palace. These historic places held a world of interest for us and recalled forgotten incidents in English history, particularly of that ill-starred personage Mary Queen of Scots.

At Glasgow we visited the great shipbuilding works on the Clyde, particularly those of William Beardmore & Co., Ltd. This plant was devoted entirely to war work, not only in the construction of ships, but in the manufacture of big guns and shells, airplanes and airships. These side issues were undertaken without any previous experience or preparation, and the success of the work is a tribute to the management. We found some labor conditions that to us were unusual. Hours of labor, for instance, surprised us. The men go to work at 6 a.m. and work until 9, when they stop for breakfast, resuming again at 9:45. A noon hour is taken at 12:30, and work is stopped about 5:30 or

6 p.m. It was admitted that the first three hours of the day's work were very inefficient, and that a straight 8-hour day would be better. To us it seemed as though a man could not be efficient if he went to work cold and hungry, with a prospect of three hours work before eating. A luncheon given us by the staff of Beardmore's gave an opportunity to discuss a number of industrial problems and compare notes on conditions at home and abroad.

That evening we were the guests of the Lord Provost and Corporation of Glasgow at a dinner at the City Chambers, where we met not only the city officials but some of the leading educators and thinkers of the community. The speeches disclosed the Scot at his best, particularly Bailie John Muir, whose homely philosophy and keen wit received sincere applause.

Armistice Prevents Bombing of Berlin

Returning to London, we visited the Handley-Page airplane factory primarily to accept an invitation for a flight, but this was prevented by a fog. We had the pleasure, however, of climbing into and inspecting a special plane which had been built to bomb Berlin, and which was to have left on its mission on Nov. 13, two days after armistice was declared. This machine has a wing spread of 127 ft., a carrying capacity of 14 tons, four engines aggregating 1400 hp., tanks for 1500 gal. of gasoline, two pits for rapid-fire guns, one fore and the other aft, and storage for five tons of bombs. The great regret of the air forces of Great Britain was that the preparations for retaliation were not advanced swiftly enough to permit the bombing of Berlin before the war ended. It was the great regret of our party that London fog was so persistent that we were unable to make a flight in London or to carry out the plan for flying across the Channel from England to France.

A Visit to Hadfield's

Although the Ministry of Munitions promptly closed all plants to visitors when armistice was declared, it was possible to visit one or two. Unfortunately we were not allowed to enter any of the great munition plants such as Gretna. There was the most cordial and free interchange of information between England and the United States while the war was on, but the practice stopped rather abruptly with the end of hostilities. Several of our party who were interested in metallurgy went to Sheffield and visited the steel works of Sir Robert Hadfield. The plant, like others throughout the country, had been greatly increased in size for the manufacture of guns and shells. An indication of one of the problems in the machine-tool trade was found in the fact that Hadfield's alone would discard 1000 lathes for which they had no use in peace times. Women had been largely employed in the plant, working at the lathes and at lighter work around the shops. At a later visit with Sir Robert Hadfield in his London home we learned something of the work his company had done in the development of manganese steel helmets and body armor. The former were superior to those used by some of the other nations, and while the latter were effective as far as protection was concerned, they were not practically useful. We saw specimens of helmets and armor that had successfully resisted rifle fire comparable to that which would be encountered in warfare. We were also given a private view of Britain's accomplishments in the line of super-shells and guns. They were not used in actual combat, but had been built and tested, and could have been put to work if occasion had demanded.

Technical Man Awaits Appreciation in England

A too brief visit to Sheffield University allowed me an hour with Prof. J. O. Arnold, who is at the head of the department of metallurgy and engineering. It is greatly to be regretted that work such as Prof. Arnold has done and is doing is not adequately supported. It seemed to me as though England had not yet risen to an appreciation of her technical men, despite the fact that they were the ones on whom she had to call when she was confronted by a foe skilled in technology and the application of science in the art of warfare. I was told that the Government had actually contemplated providing chemists for some of its works with the munificent salary of £125, about $625, per annum, a sum which would not attract a bottle washer in our American laboratories. This was but one instance of what seemed to me to be a lack of appreciation of technical education, but I was told that a change is coming and that England is alive to the needs of research, co-ordination of industry and universities, and the value of technology in the national life. Incidentally, some excellent work has been done by such men as Prof. Arnold and Sir Robert Hadfield, and we may expect some good papers from their pens.

One of those delightful informal social events that marked our stay in England was our entertainment by Sir Thomas Lipton at his home near London. We motored out in time for dinner, spent a delightful afternoon and returned after tea. Sir Thomas, of course, is known as one of the world's greatest sportsmen. His charming Irish wit and manner, coupled with his whole-souled love of sport, make him an ideal host. He told us of his hopes, which we learned later had been blasted, for a yacht race with America in 1919, and he gave us all shamrock pins which we promised to wear when the race was run. Sir Thomas has been heart and soul in the war and has done a fine work in his support of the Red Cross. On the occasion of our visit he invited Sir Andrew Weir, Surveyor General, who has charge of the purchase of Government supplies, to meet and talk with us.

Lord Northcliffe Entertains

Before leaving England we were entertained at luncheon by Lord Northcliffe, owner of the London *Times*, at Printing House Square. For this occasion our host had invited leaders of industry and political thought to meet and talk with us, and we counted the affair one of the most instructive we had attended. Sir Robert Hadfield spoke of the possibility of giving workmen a summer holiday with pay instead of making them take their holidays on their own time. Mr. W. L. Hichens, chairman of Cammel Laird & Co., spoke of his desire to improve the condition of the worker, maintain his high wages and reduce his working hours. To do this, he said, would require more money on the part of the capitalist and more work from the worker. Both labor and capital must see that they are going to profit out of

CONDITIONS IN THE COAL MINING REGION OF LENS

the improved order of things, and the community is to be the final judge of whether they are profiting enough or too much; neither should be allowed to hold the community up for ransom. He felt that the principle that "Might is Right" is what we have been fighting against in the war just closed, and that the principle was not acceptable in industry any more than it was among nations. Other speakers at the luncheon voiced interesting views on the problems that were confronting the nations of the world; all were optimistic, but earnest in the belief that the times demand new methods and ideas.

The Battlefields of France

The English Channel is proverbially a difficult piece of water for poor sailors to cross, but we were kindly treated to a comparatively smooth sea when our party crossed from Folkestone to Boulogne. Before we were able to leave London for France we were obliged to spend several very good and precious hours getting passports properly stamped. War-time travel is beset with difficulties enough to deter any but those for whom the way is smoothed as it was for us. Other civilian travelers who had not the kindly arm of the British Government about them were subjected to much delay and annoyance trying to prove their identity and show the necessity for travel between the two countries. We were practically the only civilian passengers on the boat leaving Folkestone. Arriving at Boulogne we were met by military representatives of the Ministry of Information, who took us immediately by auto to the château at Radinghem which had been provided as headquarters for American visitors. The château is a thirteenth-century structure, with moat and drawbridge, which had been fitted with some modern conveniences. Here we were comfortably quartered for several days while we made daily automobile trips of about 150 miles to various parts of the battlefront which had been lately abandoned.

Our hosts at the château were British officers who were familiar with the military history of the ground to be covered, and each night we received a brief lecture on the points to be visited the following day. Military maps were provided on which the route could be traced and points of interest noted.

Our first day's trip took us to Bethune, La Bassée, Lille, Menin, Ypres, Poperinghe, Steenvoorde, Hazebroucke. The terrific effect of modern shell fire was evident at all of these places. Our first introduction to it was at Bethune, but it was at La Bassée that we saw it at its worst. La Bassée literally has not two bricks held together by the original mortar. Houses, store buildings and churches are piles of brickbats and rubbish. Here and there we saw great concrete gun foundations and shelters, reinforced with steel. The walls and roofs of these structures were four feet thick, and the foundations much heavier. There was a great deal of this concrete work throughout the country occupied by the German forces, and the magnitude of the work recalled the quarrel that Germany had with Holland

regarding the transportation of sand and gravel across the latter country. Germany professed at the time that the material was altogether for peaceful purposes.

Devastation in the Battle Area

The destruction of cities and towns in France is so complete along the line of battle that one place looks much like another and no powers of description can enable the reader to visualize the wreckage. Occasionally small towns have been so completely wiped out that the place on the road is marked by a sign post informing the traveler, for example, that "This is Souchez." In some of the illustrations accompanying this article I have tried to give an idea of the destruction of cities, the churning of the ground by high-explosive shells, the nature of barbed-wire entanglements and trenches, etc., which are much alike throughout the length of the battlefront.

The city of Lille was not damaged by bombardment, being held by the Germans throughout the war, but when it was evacuated the bridges were destroyed at every approach to the walled city.

We crossed the Lys into Belgium at Halluin and Menin and took the Menin road to Ypres. This was the most desolate spot I have ever seen, uninhabited and uninhabitable, filled with trenches and lines of barbed wire, pitted and scarred with shell craters that were partly filled with water. The trenches in this section, in front of Ypres, were shallow and the dugouts were filled with water. At one place we saw an abandoned contractor's

CAPTURED GERMAN GUNS IN PARIS

pump that had been used to keep a dugout reasonably free from water. It was inconceivable that men could withstand the hardships of such a life as they had to live here.

Entering Ypres by the Menin gate, we traversed a part of the city and saw the ruins of the famous Cloth Hall and the cathedral, both damaged beyond repair. Although this city was never taken by the Germans, it was shelled from three sides and was practically destroyed.

Wanton Pillage of Douai

On our second day out from the château we went to Arras, Douai, Lens, Vimy Ridge and other places of less importance. Douai roused our ire more than anything we had seen because it showed the effects of wanton destruction and pillage by the Germans. Externally Douai presents the appearance of any city outside the war zone, but within its houses, stores and churches are the evidences of vandalism, plundering and despoliation, What could not be carried away by the Germans as booty was destroyed. Oil paintings were ripped from their frames, mattresses cut open and dumped on the floor, books swept from their cases and china from the cupboards, plumbing and all metal work ripped out and taken away. We found M. Paul Robaut, general secretary for the French Red Cross in Douai, whose home had been used for a long time as headquarters for the German Red Cross. He was deported from the city last September with all other inhabitants, and when he returned he found his beautiful home in such a condition of destruction as could not have been accomplished by earthquake and cyclone. Nothing but the hands of an army of German soldiers sacked Douai and left it in its present pitiable condition. Here also in one of the houses that had been used as German billets we found a German saw-tooth bayonet, a wicked instrument. We left this place thoroughly convinced that any distinction between the German people and their rulers was quite unnecessary.

The coal-mining region of Lens also presented a scene of destruction that could be accomplished only by the hands of fiends. No one knows what may be the condition of the coal mines of Lens. It is reported that they were dynamited by the Germans before they were abandoned, and that they have since filled with water. As the mines are deep and the veins narrow, it may be impossible to recover them through the present shafts. Certain it is that all surface workings have been destroyed beyond repair and the villages of the region rendered uninhabitable. The first step toward rehabilitation will have to be shelter for the workmen.

Vimy Ridge was an impressive battlefield, for it could be seen how certain death must follow the order to cross the narrow valley and assault the ridge held by the Germans. Quantities of ammunition still were stored by the roadside in huge dumps, and there was evidence of the fiercest fighting.

On the Hindenburg Line

The third day's ride took us to Albert, Bapaume and the Hindenburg Line and Canal du Nord on the road between Bapaume and Cambrai. At one point on the limestone road we saw an impressive sign "Dust Draws Hell Fire—Go Slow." Closer examination showed that originally it had read "Shell Fire," but the erasure of the S had left the sign fully as significant and appropriate as it was originally. The sign had been placed there as a caution to truck drivers in the army trains.

We spent some time at the Hindenburg Line, examining the trenches and dugouts. The latter were quite comfortable, and the line as a whole looked almost impregnable. Tanks, however, were more than equal to this line of defense, and we saw the tracks of these monstrous engines as they had forced their way over trenches, barbed wire, shell craters and obstacles of all kinds. In tank construction and operation the Allies far excelled the Germans; the British counted them their greatest achievement in land offense.

Leaving the château and our British hosts, we went to Paris. There was a marked difference in some fundamental conditions in Paris as compared with Lon-

don. Food was more plentiful and in greater variety, although it was also more expensive. Fruit was available in better quality, but at several times the price in London. Meat could be secured without ration cards, but bread tickets were necessary if one cared for bread regularly. Paris was warm, too, and this in spite of the fact that coal was scarcer than in England. This was due largely to the fact that there are central heating plants in the hotels and large buildings, insuring more efficient combustion of the fuel.

The President in Paris

We were in Paris when President Wilson arrived, and witnessed the genuine and sincere demonstration which greeted him. The English and French people were deeply interested in his coming, and we repeatedly heard expressions of astonishment at the opposition to his trip which developed in America. To them Mr. Wilson embodies our great nation and the vital assistance which we rendered at a critical moment, and it seemed to them most logical that as the head of our nation he should participate in the negotiations for peace. Furthermore his idealism appeals to the French; and in England also we heard many expressions of approval of the ideas and ideals he has advanced. His arrival in Paris was the signal for a demonstration which lasted far into the night. There were parades with banners bearing the inscription "Vive la Paix Wilson," and many other demonstrations of approval of the President of the American republic.

Only one industrial plant was open to us in France, that of Andre Citroën in Paris. This is a modern munition plant for making the French 75-mm. shells. It is equipped with American machine tools and laid out on modern lines. Considerable attention is paid to the welfare and working conditions of the employees, of whom there were 12,000. Women were employed to the number of 8000. There was a dining room seating 3500, and rest rooms where employees could take recreation during the day. Complete laboratories for chemistry, metallography and physical testing were an important part of this modern plant. Women were employed in the laboratories, holding assistant positions. Men's wages were $5 to $6 per day, and women's $3 to $4, being about twice the wages of four or five years ago.

A trip to Versailles gave us an opportunity to visit the Palace, and see the Galerie des Glaces, in which the final sessions of the Peace Conference are to be held. It was in this room that the great German Empire was formed years ago, and here it will receive its finishing touches at the hands of the Allies. En route to Versailles we stopped at the Hôtel des Invalides, where the war museum was opened to our inspection, and special permission was granted to visit the tomb of Napoleon. The latter was still encased in the sandbags that had been placed around it as protection from aërial bombs.

Champagne Cellars at Rheims

Further visits to the battlefield were made from Paris under the escort of French officers representing the French High Commission. Noyon, Rheims and Berry au Bac were thus visited. Each had its special interest which cannot be described at length here. At Rheims there was the famous cathedral, still beautiful in its ruins. We were informed that it can be restored, and we presume it will be in due time. The Pommery champagne cellars at Rheims were also an object of satisfied curiosity. These cellars are but part of great limestone workings that underlie the entire city, extending for an aggregate distance of 60 miles. The Pommery cellars alone are 12 miles in extent. French troops were quartered in these cellars during the war, and moved from one part of the city to another without observation. We were told that Pommery cellars contained 8,000,000 bottles of champagne and that 60,000,000 was the total number in the cellars of the city.

The battlefield of Berry au Bac was notable for the fighting about Hill 108, and for the engagement of 80 tanks in a French assault on the German line of trenches. The assault was successful in that the trenches were taken, but when the tanks proceeded beyond the line and exposed themselves to direct gun fire in the open, they met with disaster and only 40 escaped destruction. Forty great hulks were still on the field when we were there, helpless looking machines when disabled by heavy gun fire, although very effective in assaulting infantry lines.

The King of Saxony's Dugout

The dugouts at Berry au Bac were the most elaborate in extent and equipment of all that we saw. They formed a continuous line of communication thirty feet beneath the trenches for a distance of about two miles. In one of them, reputed to be the underground dwelling of the King of Saxony during his occupation of that part of the line, we found a fine brick mantel and fireplace, desk, chairs, mirror, bed and evidences of telephone and electric light connections. Our conductor on this occasion, Lieut. Verdier, had fought at this point and was able to give us a very interesting account of the engagement.

For a few days we were in the hands of American officers at the visitors' quarters at Neufchâteau, and from this point made a one-day trip by auto, about 160 miles, into the city of Metz. The principal items of interest were the overturned monuments of the German Emperors, the supercilious statue of the late Kaiser among the prophets on the great cathedral at Metz, and the external evidences of damage that had been wrought on the property of German sympathizers. Store signs were being changed from German to French, and there was every evidence that it would be both popular and profitable to be French or at least a French sympathizer.

France's Disabled Industries

France gives one the impression of being somewhat dazed over her recent experience, and at a loss to know just where to begin to retrieve her lost fortunes. We had a number of dinners and luncheons with their leaders of industry, who said frankly that France was in the position of having to ask preferential treatment at the hands of the other nations. One gentleman even suggested that they would like to see French goods enter the United States duty-free, and American goods pay a duty on entering France. They are alarmed at the prospect of the Germans capturing world markets before France can even rehabilitate her factories and get new machinery in running order. The Germans return

to factories that are intact, ready to turn out their products into world trade, while France must begin at the bottom and build again her principal industries. These are the things that worry France and are probably having something to do with the new terms in the extension of the armistice period.

Returning to England from France, we spent a few days in London, during which time we were entertained at tea in Stationers Hall by the Circle of Scientific, Technical and Trade Editors. This is an organization that is striving to raise the standard of editorial work and the status of the editor in England. An exchange of views for an hour or more was profitable to all of us.

The Ministry of Information gave us a farewell luncheon in London on Dec. 19, and on Dec. 22 we sailed from Liverpool on the S. S. *Carmania*. The return voyage was made without the precautions that attended our trip eastward, although life-jackets were still recommended and a boat drill was held. Our ship carried mine sweepers on either side near the bow. We were carrying about 3000 Canadian troops bound for Halifax, and on reaching that port we secured shore leave so that we might see the results of the terrific explosion in the harbor in December, 1917. We also had an opportunity to inspect the new $35,000,000 water and railroad terminal which the Government is constructing. The balance of trip down to New York was uneventful, and we landed on New Year's Day, glad that our home is in the U. S. A., but not forgetting the ties that must inevitably bind us closer to our English-speaking friends on the other side. One cannot experience two months of travel in foreign lands and contact with peoples with whom we have been united in a vital struggle without getting a new point of view, broader, larger, more comprehensive and sympathetic. We have been deeply impressed with the endurance and fortitude of the British and French, and we can but admire the high ideals that animate them in their approach to the solution of problems that concern the world's future welfare. Our own participation has been deeply appreciated, so much so that we are likely to be led into exaggeration of the importance of our part in the great struggle. At the same time our help is just as urgently sought in meeting the problems of peace, and to that end we must all lend sympathetic and broadminded aid.

Two Great Problems

There are two great problems in which we are interested: The reconstruction of French and Belgian industries, and the reparation by Germany for the destruction of life and property. Reconstruction will come slowly because there are human problems of shelter and sustenance to be solved before factories and shops and works are rebuilt. Some cities may not be rehabilitated; new sites will be chosen after due study by a central organization in Paris. Reparation, of course, must be made by Germany to the fullest extent. The German nation today is an unrepentant and unchastened people, but perhaps the size of the bill to be paid may awaken them to the enormity of their crimes against civilization. There is no need for leniency or magnanimity in itemizing the bill or exacting its full payment. The Germans are resourceful and frugal. They have learned the lesson of self-denial and saving, and they can continue in these habits and apply the product to the expiation of their crimes.

The bill will be large, but time can be allowed for its payment in full.

Synopsis of Recent Chemical and Metallurgical Literature

Die Casting of Aluminium Bronze.—H. RIX and H. WHITAKER of the British Westinghouse Co. read a paper on the above title before the March, 1918, meeting of the Institute of Metals. They point out the advantages of die castings as follows: Die castings are uniform and accurate to 0.005 in. or less; they eliminate machining and they allow a high, continuous output. The cost of the casting should be analyzed, adding the proportional cost of the die, which is apt to be very large, in making a comparison to the sand casting, where machining must be added. Die castings were made more than twenty years ago of low-melting white metals. The many advantages of aluminium have been nullified by its high melting point; by the fact that it attacks iron when hot, thus reducing the life of the dies to as low as two thousand casts; by its weakness when hot and by its high shrinkage. The latter has been reduced to 1.4 per cent by proper alloying.

Successful castings in quantity are made by the authors using bronzes containing from 7 to 10 per cent aluminium and 1 to 4 per cent iron. The effect of the iron is important. Some iron and aluminium enter into solid solution with the copper, forming the alpha-constituent, but the bulk of it probably separates out as a high-melting point compound like $FeAl_3$, which forms a skeleton in which the residual metal solidifies. This refractory skeleton thus reduces the shrinkage and produces a fine grain. The iron also increases the yield point and ultimate strength at the expense of ductility. The properties of the finished casting vary with the heat treatment, the speed of cooling, the temperature of the metal, of the mold, and of stripping. Fortunately the above alloys show no beta-constituent; therefore it is not so responsive to heat treatment as though this metal were present. The alloy cast in a 1-in. chill gives the following tests:

Diameter of test section, in.	0.564
Yield point, lb. per sq.in.	29,400
Ultimate tensile strength, lb.	71,000
Elongation in 2 in., per cent.	24
Reduction of area, per cent.	21.8

For a scientific investigation into die casting, the authors point out the following points for study in the alloy to be used: Its coefficient of expansion at different temperatures, fluid and solid; its specific heat; its thermal conductivity; its mechanical properties at high temperatures; its mass, volume and surface area when cast; its latent heat of fusion; its metallography; its pressure on the die, and its fluidity.

The discussion of the paper brought out the fact that the iron should be added to the alloy as pure wrought iron chips, silicon in the addition being fatal. The metal should be melted at as low a temperature as possible and properly killed, the melting practice being responsible for many blowholes and other defects. The cores should be removed at the right time so that by shrinkage the solidifying metal about them might not rupture through setting up internal strains. In some cases the handling of cores was so difficult that openings could be more cheaply machined. Bottom gating gives a flow of metal which has a cleaning effect on the molds, but which requires more gates, vents and risers. Aluminium in alloys seems to protect the cast iron dies by the formation of a skin of alumina; this is quite an advantage over brass, as the latter forms a zinc oxide coating which must be carefully cleaned out between casts. Success in die casting involves starting with relatively simple forms, and then the expenditure of much capital, patience and brains in working to more complicated castings.

The approved material for dies is a chill-cast block of close-grained, gray cast iron, as hard as can be machined. Two analyses quoted were:

	Per Cent	Per Cent
Combined carbon	0.14	0.84
Graphitic carbon	3.35	2.76
Silicon	2.40	2.02
Manganese	0.43	0.29
Sulphur	0.10	0.07
Phosphorus	1.3	0.89

The latter is perhaps a little high in combined carbon, as this element causes growth and deformation in the hot die. The former is also too high in phosphorus. A well made die with these specifications will stand from five to seven thousand casts with the aluminium bronze under discussion, and then fail by the development of small cracks at right angles to the axis of the piece, especially where there is the largest heat transfer. No facing is required, the fine particles of graphite in the metal effectually acting as a lubricant. This graphitic sponge also allows the ferrite matrix to expand more readily and with less internal stress than would be the case in a close grained block of steel or nickel. No special cooling of such dies is required. Each casting is matter of individual study—for that matter, different alloys may not be cast successfully in the same die, owing to their different requirements in shrinkage, gating, etc. About the only advice which can be given as to the design of dies is that the mass of the metal should be such that the rate of cooling of the contained liquid metal should be at the same rate in all parts. The core-plugs are made of chrome-tungsten steel, and are dipped in graphite wash after they are withdrawn, but even so they last only from one-half to one-third as long as the die.

Evaporation of Small Spheres.—IRVING LANGMUIR (*Physical Review*, Vol. 12, p. 368) assumes that evaporation of small objects in air should be closely related to the convection of heat from bodies of the same shape. Previous researches on the latter (ibid., series I, vol. 34, p. 401) had shown him that the loss of heat from small wires consists essentially of conduction through a film of relatively stationary gas around the wire. Thus he believes that the air in contact with small evaporating spheres (of iodine, for instance) is saturated, that the exchange of molecules between the solid and its surrounding vapor is very rapid compared with the rate at which the vapor can diffuse away through the air and that no allowance need be made for air currents. On this basis a formula is developed which shows that the rate of evaporation is proportional to the radius of the sphere—as previously determined experimentally by H. W. Morse—and from which, using Morse's results, the diffusion coefficient of iodine vapor in air at 20 deg. C. is calculated to be 0.053, a figure in harmony with known coefficients for vapors of high molecular weights.

Convention of National Foreign Trade Council

The National Foreign Trade Council will hold its sixth national foreign trade convention at the Congress Hotel, Chicago, on Thursday, Friday and Saturday, April 24, 25 and 26, 1919. The formal call will be issued shortly by the chairman of the council, Mr. James A. Farrell, president of the United States Steel Corporation. The convention will deal with foreign trade as a factor in stabilizing American industry—problems involving the conversion of war industries to the needs of peace; development of our foreign trade to provide employment for our soldiers, sailors, and war workers; and the formation of a definite policy dealing with the future of our new shipping.

Imports and Exports of Gold and Silver

The Bureau of Foreign and Domestic Commerce reports that imports as well as exports of gold continued to decrease during the latter part of 1918, the imports amounting to $62,000,000 in the calendar year, against $552,000,000 in 1917, and the exports to $41,000,000, against $372,000,000. Imports of silver increased from $53,000,000 in 1917 to $71,000,000 in 1918. The exports of silver during December, 1918, amounted to $48,000,000, a larger amount than in any month during the past three years. For the calendar year 1918, exports of silver amounted to $253,000,000, against $84,000,000 in 1917.

Employees of Copper Companies to Meet Secretary of Labor

The Secretary of Labor invited the grievance committee of employees of all the copper companies operating in Arizona and representatives of labor in Utah and Montana to send delegates to confer with him in Washington on Jan. 31 regarding labor conditions in the copper districts. The copper industry is confronted with grave conditions owing to the reduction of output and employment, and it is the purpose of the Department of Labor to cooperate in securing the best working conditions during the period of readjustment.

Meeting of the Canadian Mining Institute

The Canadian Mining Institute will hold its twenty-first annual meeting at Montreal, Canada, March 5 to 7. A special invitation has been extended to the members of the American Institute of Mining Engineers to attend and participate in this meeting. March 6 will be American Institute of Mining Engineers day. As at the New York meeting of the A. I. M. E. in February, there will be a discussion on international co-operation in mining and uniform mining law for North America at the C. M. I. in March.

Book Reviews

THE ZINC INDUSTRY, By *Ernest A. Smith*, Assoc. R. S. M. 211 pages, illus. Price $3.50. New York: Longmans, Green & Co.

This is one of the excellent "Monographs on Industrial Chemistry" edited by Sir Edward Thorpe, designed to give the average reader a clear view of certain important manufacturing processes as influenced by chemical phenomena. Therefore, while this particular book does not attempt to present the details of mining, metallurgy and selling, more ambitious writers could do well to present their material in a manner as clear and inclusive. For instance, it contains well selected and easily understood data on the metallography of pure zinc and its common alloys, even including the more modern zinc-base die casting compositions. In view of the economic and commercial aspect of the metal, the author is necessarily influenced by his British citizenship; a foreshortened view of the technology is fortunately easy to avoid. In the chapter "The Rise and Progress of the Production" is an instance of the oft-recurring cycle of events. One notes the fact that the manufacture of brass from liquid zinc was long neglected for the ancient process of cementation by calamine, until finally the Prussian industry in 1825 (pointing the way for the American Zinc Institute) offered prizes for the discovery of new uses for zinc metal. American producers would also profit from the pre-war decadent condition of the British spelter industry as compared with that on the Continent, due, as the author states, to neglect of modern progress in plant design, to a lack of scientific control of the process, to the absence of co-operation among producers, and to the failure to build and maintain an adequate supply of skilled workmen.

* * *

BIBLIOGRAPHY OF FOREIGN TRADE PUBLICATIONS. By *Herbert Stanley Shuey*. 78 pages. Price $1.50. San Francisco: The ten Bosch Co.

This compilation of references on foreign trade will be a distinct aid to those business houses, banks, manufacturers and others who expect to participate in export business. The author, who is lecturer in commerce at the University of California, has gathered together only those sources which are recognized as authoritative, including publications of the Bureau of Foreign and Domestic Commerce and other Government papers. References are grouped under appropriate heads such as commercial policies and tariffs, directories, export journals, financing, foreign markets, geography and commerce, insurance, statistics, theory and international trade, transportation and trade routes and year books.

Personal

CAPTAIN EDWARD E. ASHLEY, JR., formerly consulting mechanical and electrical engineer for Starrett & Van Vleck, New York City, has resigned his commission in the Air Service of the U. S. Army, to accept the appointment as sales engineer of the Mercury Mfg. Co., Chicago, Ill.

DR. D. D. BEROLZHEIMER, librarian of the American Chemical Society, 1910 and 1911, librarian of the Chemists' Club, 1910 to 1915, and librarian of The Barrett Co., New York, since April, 1915, has severed his connection with the latter firm and is now assistant technical editor with the Chemical Catalog Co., 1 Madison Ave., New York City.

BRADLEY, BRUFF & LABARTHE have been retained by the Penarroya Mining & Metallurgical Co. of Paris to design a complete lead smelting and refining plant to be erected at Penarroya, Spain.

MAJOR F. E. BREITHUT, Chemical Warfare Service, has been detailed by the War Department to the War Trade Board to act as chairman of the chemical group of the price section. This group is engaged in a study of price fluctuation of chemicals during the war and an analysis of its cause and consequence. Associated with Major Breithut are Mr. F. W. Cassebeer, Capt. P. W. Carleton, Lieut. Chas. L. Fry, Lieut. W. N. Jones, Mr. H. L. Lewenberg, Capt. W. Lee Lewis, Mr. W. B. Meldrum, and Capt. H. L. Trumbull.

CAPT. DECOURCY BROWNE, Ordnance Department, U. S. A., expects to return to the United States from France in the near future and will be located at the Engineers' Club, 32

W. 40th Street, New York. Captain Browne, before entering the service, was metallurgical engineer of the Metal & Thermit Corporation, New York.

Col. G. A. Burrell, recently of the Chemical Warfare Service, has opened an office as consulting chemical engineer in Pittsburgh, Pa.

Mr. C. W. Cromwell of the engineering firm of A. G. McGregor, Warren, Ariz., is in New York City.

Mr Clarence T. Emrich resigned his position as chief chemist with the Old Dominion Co. to accept the position of assistant superintendent with the International Smelting Co. at Miami, Ariz.

Major A. C. Fieldner, Chemical Warfare Service, U. S. A., who was in charge of the gas mask research at the American University Experiment Station, Washington, D. C., has returned to the Pittsburgh station of the Bureau of Mines, where he will have charge of the chemical research laboratory.

Mr. Francis N. Flynn, manager of the Consolidated Mining and Smelting Co., Trail, B. C., has resigned to become assistant general superintendent of the Balbach Smelting and Refining Co., Newark, N. J.

Mr. Daniel Guggenheim has been succeeded as president of the American Smelting & Refining Co. and the American Smelters Securities Co. by his brother, Simon Guggenheim, formerly U. S. Senator from Colorado. Messrs. Murry Guggenheim and S. R. Guggenheim also retire from the active management of the companies.

Mr. F. H. Hawkins, who for several years past has held the position of chief assayer for the Standard-Silver Lead Mining Co. of Silverton, B. C., has gone to Anyox, B. C., to accept an appointment with the Granby Consolidated Mining & Smelting Co. Mr. Thomas Brown will succeed him at the Silverton assay office.

Mr. A. A. Heller, treasurer and general manager of the International Oxygen Co., has given up his active managerial duties. Mr. Eugene Schoen has been appointed general manager for the company. Mr. Heller, as treasurer, continues in charge of the financial departments of the business.

Mr. Frank J. Herman, formerly with W. J. Rainey and more recently manager of the coke section of the United States Fuel Administration, has resigned to accept a position as assistant to the president of the Rainey-Wood Coke Co., which is building a by-product coke plant at Swedeland, Pa.

Arthur D. Little, Inc., announces the following additions to its technical staff: Mr. Robert Woods Van Kirk, M. I. T. 1918, chemical engineer; recently engaged in the development division of the C. W. S., stationed at Cleveland, Ohio. Mr. John Stevens, M. I. T. 1918, chemical engineering administration; recently served as a private in the research division of the C. W. S., engaged upon gas defense work, stationed first at Washington and later in the Little laboratories. Lieut. Earl Place Stevenson, Wesleyan College, Middletown, Conn., 1916, B. S.; instructor in organic chemistry at M. I. T. 1917 and 1918; recently engaged in the research division, C. W. S., Washington and Boston. Mr. Eric R. Jette, Franklin and Marshall, Lancaster, Pa., 1918, B. S.; engaged as a civilian in the pyrotechnic section of the research division, C. W. S., Washington. In addition, the following members of the staff who had left the company's employ for governmental activities have returned to the staff: Mr. Harrison E. Howe, consulting chemist, Ordnance Department at large, assigned to the nitrate division, Army Ordnance, for the purpose of correlating the research being conducted in various laboratories on the fixation of atmosphere nitrogen, with which division appointment is still held. He is also commissioned Major, Ordnance Section, Officers Reserve Corps. Lieut. Roy C. Charron, who was first chemist for the division gas officer at Camp Devens, Mass., and later assistant to chief of the emergency laboratory section, polytechnic division, C. W. S., American University, Washington, D. C. Mr. J. M. Cullen, who was in the U. S. Navy.

Major George L. Norris, engaged in aircraft production, has received his honorable discharge from the Army and has returned to his former position as metallurgical engineer with the American Vanadium Co., Pittsburgh. Major Norris was district manager of production, Pittsburgh office, until Nov. 1, when he was transferred to Washington and assigned to duty as chief metallurgist, raw materials department, Bureau of Aircraft Production.

Mr. M. G. Spencer, formerly connected with the Midvale Steel Co. and later with the Watertown Arsenal, in the capacity of chief chemist, has joined the staff of the Electric Steel Co. of Indiana, Indianapolis, Ind., in charge of metallurgical operation.

Mr. E. E. Thum, Western editor of Chemical & Metallurgical Engineering, addressed the Utah Section of the A. I. M. E. Jan. 24, the subject being "Economic Situation of Certain War Minerals." Mr. Thum has also been asked to talk on the Nebraska potash industry before the Utah Society of Engineers, which is holding a symposium on potash on Feb. 19.

Mr. John T. Ward, who has been with the National Carbon Co., Inc., as chemical engineer at the Cleveland works, has been transferred to the New York office of the company as assistant to the works manager.

Mr. A. P. Watt, consulting engineer, of New York, has opened an office in Boston, where he will continue to specialize on ore concentration.

Mr. Henry Wigglesworth, of the National Aniline & Chemical Co., will take a leave of absence to serve for a time as a trade commissioner for the Bureau of Foreign and Domestic Commerce to study the dyestuff and textile conditions in France.

Obituary

Mr. Frank Baird, a graduate of the University of California, died recently at his home in Westwood Park, near San Francisco, following a brief illness from influenza and pneumonia. Mr. Baird was associated with his brother, Dudley Baird, in the Pacific Foundry Co., San Francisco. He is survived by his wife, to whom he was married last September, and by two brothers.

Lieut. Charles F. Hawkins died at the home of his parents on Dec. 27, 1918, of pneumonia following influenza. In August, 1917, he accepted a position as professor of chemistry at Williams College, resigning in February, 1918, to enlist with the Chemical Warfare Service. He was mustered out of the service Dec. 21 and returned to his home Dec. 23.

Mr. Ernest H. Simonds, metallurgical engineer, died at Oakland, Calif., Dec. 26, of influenza. Mr. Simonds was a graduate of the University of California and for a long time was instructor of assaying at that institution. Many of the California graduates will hear of his death with keen regret. After leaving the University of California, Mr. Simonds opened an assay office in San Francisco. The business was successfully established and was continued until the San Francisco earthquake and fire wiped it out. Simonds went next into metallurgical engineering, and established himself in a good practice.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, Jan. 25.—The non-ferrous market is still lagging, while producers are reluctant to make sharp reductions enough to stimulate buying.

Aluminium:—The Government prices on ingots 98 to 99 per cent Al are $660 a ton f.o.b. plant in 50-ton lots; $662 down to 15-ton lots; and $666 down to 1-ton lots, which prices will continue until the first of March. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

Antimony:—Wholesale lots of antimony are being offered at 7½c. while small lots bring from 7⅝c. to 7¾c. per lb.

Copper:—Prime lake is nominal at 23c. Electrolytic is selling at 20½c. and casting at 19c. The producers are determined to hold their prices high believing that the foreign demand will soon be strong.

Copper sheets, hot rolled	lb.	$0 29 —	$0.33
Copper sheets, cold rolled	lb.	.30 —	.34
Copper bottoms	lb.	37 —	.41
Copper rods	lb.	25¾	..
Copper wire	lb.	23	..
High brass wire	lb.	24½—	26¾
High brass sheets	lb.	24½—	26¾
High brass rods	lb.	23½—	25¾
Low brass wire	lb.	26½—	28¾
Low brass sheets	lb.	26½—	28¾
Low brass rods	lb.	27½—	29¾
Brazed brass tubing	lb.	35½—	37¾
Brazed bronze tubing	lb.	40½—	42¾
Seamless copper tubing	lb.	35 —	37
Seamless bronze tubing	lb.	40¾	.40¾
Seamless brass tubing	lb.	34 —	36
Bronze (gold) powder	lb.	1 00 —	1.75

Lead:— Great interest is evidenced in the action to be taken by the Senate on cancellation of war contracts, among which lead occupies a conspicuous place. Spot New York is quoted at 5.45c. to 5.5c. per lb. and St. Louis at 5c. to 5.2c.

Tin:—The U. S. Steel Products Co. has liquidated 3000 tons of the original 10,000-ton stock at the 72c. basis. It is expected that it will take several months to dispose of the remaining stock, after which prices will fall sharply.

Zinc:—Spelter continues its gradual decline, with spot New York at $144 to $145 per ton; East St. Louis, spot $138, Jan. $137, Feb. $136, March $135 and April $134.

OTHER METALS

Bismuth	lb.	$3 50 —	$3 65
Cadmium	lb.	1 50 —	
Cobalt	lb.	2 50 —	3 50
Magnesium	lb.	1 75 —	2 10
Mercury	75 lb.	105 00 —	
Mercury	lb.	1 95 —	
Nickel	lb.	.40 —	45
Tungsten	lb.	34 00 —	
Iridium	oz.	175 00 —	
Palladium	oz.	135 00 —	
Platinum	oz.	105 00 —	108 00
Silver	oz.	1 01½—	

The Iron and Steel Market

The rate of production on both pig iron and steel continues to decline, being in steel ingots and castings perhaps 60 per cent of capacity at the close of January, as against 80 per cent at the beginning of the month, and about 90 per cent during each of the last four months of 1918. The rate may easily, from present indications, fall below 50 per cent before the end of February. Pig iron production has not declined as much as steel production, and for this divergence various reasons may be assigned. There is a fair consumption of pig iron by foundries, and indeed some foundries, whose operation was greatly curtailed during the war, are more active. Steel works are under contract for pig iron and not for scrap, and on that account may be using a higher percentage of pig iron and a lower percentage of scrap, although the cheaper production would be by using more scrap, as scrap has declined greatly in price and pig iron is down only $3.

From a general survey of the situation the astonishing thing is not that steel production is so light, but that it is so heavy. There appears to be scarcely any demand for steel, and yet a 50 per cent operation of the present capacity means 1,500,000 gross tons per month of finished rolled steel. The Fleet Corporation is mentioned as the largest steel consumer, but during its period of greatest pressure for steel it was calling for only about 250,000 gross tons a month, and it then accumulated a surplus which it now desires to reduce. Next, the automobile industry is spoken of as a good customer of the steel industry, but it would do well to consume 100,000 tons of steel a month. As to the railroads, they are taking scarcely any rails or structural steel, but there is a very fair rate of locomotive production, and about 75,000 freight cars of the 100,000 ordered by the Railroad Administration last April are still to be delivered and the manufacture of those cars is proceeding at a good rate.

Roughly speaking, about one-third of the present steel production is against new orders booked from week to week and about two-thirds is against old orders, which, of course, are gradually playing out. The new orders are increasing slowly, not as rapidly in point of tonnage as old orders are completed, and thus the trend in production is downward. A distinct improvement in demand is expected with early spring and it depends upon how far the decline in production has gone by then whether the increase in new business will be sufficient to arrest the decline and produce an increase in operations.

Prices

Prices of pig iron, unfinished steel and finished steel are being held rigidly. There can hardly be any question about this, as all producers are watching the market situation very closely, and evidently with the intention of meeting price cutting if it occurs. No mill intends to permit another mill to "get away" with a "gumshoe campaign" such as have sometimes been conducted in the past in somewhat similar circumstances. The theory once entertained in many quarters that it would be possible for demand for iron and steel to revive with the present price level maintained is now almost everywhere abandoned. Views of the general economic situation from all angles are that there must be a general reconstitution of commodity and labor values. Commodity prices cannot stay up because labor costs are high, and labor costs cannot stay up because commodity prices are high. They did not help keep each other down during the war, and they are powerless to keep each other up in future. New construction and development are essential to industrial activity and prosperity, and the new things to be created could not compete with those in existence. While the cost of both commodities and labor has greatly increased, the intrinsic value of the material wealth of the country has not been similarly marked up, and in the long run it will exercise an important controlling influence. In the iron and steel industry proper there is no prospect that wage rates will experience any great decline in the near future, not for six months or more, but there will be an increase in labor performance, whereby labor cost will be reduced. In the activities that normally are the great steel consumers, particularly building and construction work of all sorts, a great decrease in labor costs is to be expected, through better labor performance, through the disappearance of premium rates and bonuses, and perhaps through some declines in actual wage rates.

Steel Contracts

After giving more or less favorable consideration to the new form of steel sales contract for several weeks, the directors of the American Iron & Steel Institute voted on Jan. 24 not to recommend any contract for adoption by the steel mills, and to discharge the contract committee that had been in existence for several years. The proposed contract form was drawn up with the object of making contracts binding in the finished steel trade and eliminating the practice of considering them options given by the producer to the buyer. Its important features was two paragraphs providing for the payment of "liquidated damages" by the mill if it failed to ship on time or by the buyer if he failed to specify on time. The object, of course, was not to make it that there would be large payments of this sort, but to make it that contract engagements would be so made that they could be lived up to. Those who advocated the new contract pointed out how "unbusinesslike" is the customary method of doing business, and how different it is from practices in other industries. Apparently they did not attach much importance to the fact that under the practices complained of the steel industry has been very successful, with practically no failures and with good profits except in periods of depression when such contracts did not exist.

The Next Active Period

The belief continues that there is in store for the iron and steel industry a period of several years of great activity and prosperity, the chief question being when that period will begin. There can, of course, be a full demand for the tonnage of steel that can now be made, 40 per cent greater than the capacity existing in 1914, only when there is great activity in new construction of all sorts. Construction costs must come down and the prospective investor must otherwise be assured that his investment will prove profit-

able. The only thing clear is that such a condition does not exist at present. It seems fair to assume that the peace settlement must be completed, the menace of bolshevism removed and the future status of the railroads determined.

Chemical Market

COAL TAR PRODUCTS:—Many of the operators in coal tar products regard the period of uncertainty now prevailing but temporary, although predictions vary when business will again open up and there are those who are not disposed to take an aggressive stand one way or the other. On the other hand, however, it is generally conceded that the coal tar industry has developed to such enormous proportions that the growth will result in a reduction of cost in production, which will mean lower prices to the consumer, therefore bringing about a more favorable market for American products under the heading and it appears to be the consensus that prospects for the near future are bright. In the meantime the general tone of the market is quiet, with most of the crude products but phenol and toluol holding firm in price, although the latter item has maintained a more steady position in the market at the recent decline.

Xylol: — The result of the Government's release of this item has been felt in the market, the spot situation being much easier, while the consuming demand is fairly steady and prices are firmly maintained.

Aniline Oil: — Most producers have now reduced their prices to the level of other manufacturers of this product, but there continues to be a lack of interest generally displayed about the market, with trading in small lots being the only movement noted.

Paranitraniline: — The lack of demand combined with keener competition has brought about a lower market for this product, offerings of which attract no important buying interest, despite the price concessions generally made, particularly by weak holders in the resale market.

Paraphenylenediamine: — The item is one of the coal tar products that has maintained a rather firm position in the market and most factors in this line report a fair volume of business passing. Quotations in the general market would indicate no important price changes.

H Acid: — Available supplies of this product are more than sufficient to meet the current call and a decline in price has been general throughout the market.

Sulphanilic Acid: — Many users of this material have their own facilities for production. However, beyond this situation there has been no pressing demand on the part of consumers, but on the contrary, trading has been very quiet and prices in most instances were subject to a decline.

Mixed Toluidine: — This market remains without special feature. Quiet trading is generally in evidence and prices have also been reduced 10c. to 15c.

Naphthaline: — A fair resumption of buying interest has taken place for this product and the market remains steady with prices quotably unchanged.

Phenol :— There has been no indication of any return to more normal trading for this crude, which is subject to a very unsettled position, with resale offerings being made in liberal quantities at such prices that the actual producers, who are striving to maintain at least a fair market, are apparently unable to create any buying interest.

Benzol: — There is a fair volume of business passing for this product, but trading is not in such important quantities to effect stocks on hand, which are available in liberal lots. Material in tank cars and the prices asked for that in drums remain at the previous levels.

Metaphenylenediamine: — While offerings of this material on the spot are none too liberal, there is little demand on the part of consumers and no difficulty is experienced in meeting the current call. The recent price concessions have seemingly originated no important interest on the part of buyers.

Orthotoluidine: — The item was sharply reduced in price, due to keener competition and the lack of demand, but prices apparently do not figure, from a buyer's viewpoint, as consumers have not changed from their disposition in buying only for their immediate needs.

HEAVY CHEMICALS:—There has been a continued lack of buying interest in most all the items under this heading. The marine strike, which did not reach a climax, it was feared would be a considerable handicap, but the trouble had a sudden end and the favorable reaction anticipated has not developed in any important volume, although export trading has shown signs of life. Declines in prices have been quite evident but not general, and it is unlikely that there will be any continuation of downward prices to the levels of pre-war trading. The spot market is seemingly controlled by second hands, with the actual producers not disposed to meet these lower prices. They claim that, up to the present, conditions have not been such to compel meeting this competition, the result being producers' figures are generally the outside.

Soda Ash: — A weak and unsettled market is quite evident for this material, with single bags sold during the week as low as $1.40 per hundred pounds. Bags from the warehouse were available at this figure up to the close with prices on a parity in Philadelphia, and in Chicago $1.65 was asked. Barrels ex-warehouse were quoted at $1.85 per hundred pounds, while double bags in the Middle West were held at $2.15 to $2.25 per hundred pounds.

Caustic Soda: — A more favorable inquiry was noted for the 76 per cent solid, but trading has not been in any appreciable quantities and sales were consummated at 3c. ex-store-New York and $3.20 to $3.25 f.a.s. The undertone of the market, however, appeared to be steadier and resale lots were quoted at from $3.15 to $3.20 per hundred pounds, ex-warehouse and $3.25 to $3.35 f.a.s. Producers generally quote future shipments at 3¼c. per pound, basis 60 per cent. Ground caustic is generally quoted at $4.10 to $4.35 per hundred pounds, but sales are only in occasional small lots.

Bleaching Powder: — Export drum material appears to have been the only item that was subject to any important call, with sales passing at 3c. f.a.s. The product in domestic drums was subject to no particular call and offerings from the warehouse were made at $1.90 per hundred pounds, while export drums at Niagara were quoted at 2½c.

Copper Sulphate: — A rather brisk business for export purposes, particularly to north Europe and Greece, is passing, while local trading is rather quiet. Standard 99 per cent plus large crystals are offered at 8¾c. per pound in large quantities and small crystals, 98½ per cent test, are offered at 8¼c. per pound in carload lots.

Formaldehyde: — Resale lots reached the market at prices ranging from 22c. to 22½c. per pound and sales were reported to be passing at this figure. There is no liberal supply on hand and producers offer no encouragement for the immediate future, but are offering late February shipments at 23c. per pound.

Chlorate of Potash: — Operators in this commodity experienced a fair trading for export purposes and contracts in appreciable quantities have been placed with the domestic trade. Quotations remain firm at 40c. per pound ex-store and f.a.s.

Bichromate of Potash: — Forward shipments are offered at 37c. per pound through second hands, while producers are now offering spot material at the same price, and for large orders this price can be done f.a.s.

Caustic Potash: — Sales have been consummated for 88 to 92 per cent in the resale market as low as 52c. There is a lack of demand in evidence, which has seemingly brought about a lower market for this product, despite the fact that some large manufacturers have been striving to maintain prices, and as high as 67c. is being asked. There were offerings from a western source at 58c. per pound for the 88 to 92 although as low as 55c. was quoted for large quantities.

Cream of Tartar: — The item continues to be neglected to a very noticeable extent and offerings of the product are now made at 60½c. to 61½c. in barrels and 62½c. to 63c. in kegs ex-warehouse.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET JAN. 10, 1919

Acetic anhydride	lb.	1.00 —	1.25
Acetone	lb.	.25½ —	.25½
Acid, acetic, 28 per cent	cwt.	3.50 —	3.75
Acetic, 56 per cent	cwt.	7.00 —	7.50
Acetic, glacial, 99½ per cent, carboys	cwt.	14.50 —	15.00
Boric, crystals	lb.	.13½ —	.15
Citric, crystals	lb.	1.25 —	1.27

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

GLOBE.—The city has awarded the contract for the construction of a sanitary sewerage system and sewage disposal plant, to include two Imhoff tanks, two sludge beds, one chlorinator house, etc., to the Clark & Henery Construction Co., Stockton, Calif. Estimated cost, $226,530. Noted Nov. 30.

PHOENIX.—The United Verde Extension Mining Co. has awarded the contract for constructing various buildings at its mine here, to Paul Michelson, Phoenix, percentage basis. About $500,000 will be expended.

Colorado

BOULDER.—The Colorado Pitchblend Co. will build a concentration mill at its mine at Jamestown and is in the market for milling equipment and lumber. Estimated cost, $300,000. J. F. Barnhill, manager.

TELLURIDE.—The Tomboy Gold Mines Co., Ltd., will build a new mill at its mine at Savage Basin and is in the market for oil flotation equipment. Estimated cost, $150,000. D. A. Herron, manager.

Connecticut

BRIDGEPORT.—The Bridgeport Hospital, Grant St., will build a pathological laboratory on Mill Hill Ave. Estimated cost, $50,000.

Illinois

ALTON.—The Western Cartridge Co. will build an addition to its brass mill and convert part of its present plant into a factory for the manufacture of brass novelties.

CHICAGO.—Goldsmith Bros. Smelting & Refining Co., 29 East Madison St., will build a 125 x 150 ft. plant addition, on 59th St. and Throop St. A. Woltersdorf, 138 North La Salle St., architect.

CHICAGO—The Trustees of the University of Chicago, 134 South La Salle St., will build a laboratory and hospital near the Cook County Hospital. Estimated cost, $400,000.

CHICAGO HEIGHTS.—The Armour Fertilizer Works, Union Stock Yards, Chicago, is having plans prepared for the construction of a one-story, 240 x 520 ft. fertilizer plant. Estimated cost, $500,000. R. C. Clark, c/o company, architect.

WOODRIVER.—The Tidewater Oil Co., Constable Hook, Bayonne, N. J., will build an oil refinery here and extend its pipe line from Woodriver to Tulsa, Okla.

Indiana

LAFAYETTE.—C. S. Barnes is in the market for a second-hand concentration and flotation mill.

Kansas

COTTONWOOD FALLS.—The city has retained Black & Veatch, engineers, Interstate Building, Kansas City, Mo., to prepare plans for complete sewerage system and sewage disposal plant. W. P. Penny, city clerk.

PRATT.—The city has awarded the contract for the construction of a new school, to include a chemical laboratory, to William Foley Construction Co., Dodge City. Estimated cost, $157,087.

Maryland

BALTIMORE.—The city is having plans prepared by L. J. Houston, Jr., engineer, 602 Parkwyrth Ave., for the construction of a sewage disposal plant. Estimated cost, $80,000.

BALTIMORE.—The city will build thirty-two filter operating tables for the Lake Montebello filters. Estimated cost, $26,000. Walter E. Lee, City Hall, engineer.

BALTIMORE.—The Hess Steel Corporation, Biddle St. and Loneys Lane, will receive bids in February for enlarging its plant. Improvements include several one story steel and reinforced-concrete buildings to conform with present structures, additional electric furnaces, rolling mills, etc Estimated cost between $100,000 and $150,000.

Michigan

DETROIT.—Fire recently damaged the chemical plant of F. F. Ingraham Co., 409 West Lafayette Ave. Loss, $100,000.

PONTIAC—The city will install Imhoff tanks and build extensions to treat sewage and prevent dumping it into the Clinton River. Estimated cost, $250,000. H. H. Barnett, City Hall, engineer.

WYANDOTTE.—The city has awarded the contract for the construction of an addition to its filtration plant and pumping station,to the Pitt Construction Co., Fulton Building, Pittsburgh, Pa. Estimated cost, $250,000. Noted Oct. 15.

WYANDOTTE.—The city has awarded the contract for the construction of a rapid sand filtration plant, also an addition to the existing pumping station, to the Pitt Construction Co., Fulton Building, Pittsburgh, Pa. Estimated cost, $185,484. Noted Dec. 15.

Minnesota

CUYUNA.—The Northern Minnesota Ore Co. plans to construct a crushing plant at its Northland Mine and is in the market for grizzlys, feeders, crushers, picking belts, conveyor belts, etc. Estimated cost, $10,000. A. K. Knickerbocker, superintendent.

MANGANESE—The village will soon award the contract for the construction of a sewerage system, to include a sewage disposal plant, septic tank, etc. J. F. Wolff, engineer.

Missouri

CAVE SPRINGS (Chitwood P. O.)—E. James, Connor Hotel, Joplin, will move and erect a complete second-hand mill here.

KANSAS CITY.—The city will build a complete sewerage system and disposal plant. W. B. Penny, city clerk.

VALLEY PARK.—The Universal Glass Company, of Pennsylvania, has acquired a glass plant here comprising eleven acres, and will reopen, remodel and reequip same for its own use. Address owners through R King Kauffman, Mercantile Trust Building, St. Louis.

WACO.—The Waco Mining Co. will build a complete new mill and is in the market for engines, boilers, hoists, crushers, rolls, pumps, rock drills, etc. P. B. Butler, manager.

WEBB CITY.—Crocker Bros. have submitted a plan to the Chamber of Commerce for the construction of a fertilizer plant here, in connection with their packing plant. Project will be investigated. Estimated cost, $50,000.

Montana

HAVRE.—The Board of Health will submit plans not later than May 1, for the installation of a sewage disposal plant. C. W. Swearingen, city engineer.

Nebraska

LAKESIDE.—The Omaha Potash & Refining Co. will install evaporators, coal handling machinery, dryers, crushers, oil engines, etc., in the plant which it plans to build 20 miles south of here. Total estimated cost, $1,000,000. D. E. Wynn Jones, superintendent. Noted Jan. 15.

Nevada

PIOCHE.—The Virginia-Louise Mining Co. plans to install a new compressor plant and enlarge the ore bins at its mine about 4 mi. southwest of Pioche. R. T. Walker, superintendent.

PIONEER.—The Consolidated Mayflower Mines Co. plans to rehabilitate its mine here. Improvements include a new ball or tube mill, new regrinding machinery and the possible enlargement of the regrinding plant. Estimated cost, $10,000. J. B. Kendall, manager.

New Jersey

JERSEY CITY—The Hoboken Electric Chemical Co. submitted lowest bid for supplying Water Department with chloral lime, at 9c. per lb. for liquid chloride and 2.8c. per lb. for bleaching powder.

LINDEN.—The Transatlantic Chemical Co. has awarded the contract for the construction of a two story, 100 x 150 ft. factory, to M. Byron & Co., 430 Westfield Ave., Elizabeth. Estimated cost, $100,000.

NEW BRUNSWICK.—The Bureau of Yards & Docks, Navy Department, Washington, D. C., has awarded the contract for the construction of a sewage disposal plant at the barracks, here, to Hugh S. Roberts & Co., 1122 Broadway, New York City, N. Y.

New York

NEW YORK.—Bids will be received by Nicholas J. Hayes, Commissioner of Water Supply, Gas & Electricity, Room 2351, Municipal Building, until Feb. 5, for furnishing and delivering liquid chlorine and chloride of lime.

BROOKLYN.—Moller & Schuman, Gerry and Wallabout St., will alter and build extensions to their varnish plant. Estimated cost, $80,000.

CENTRAL ISLIP.—The State Hospital Commission, Albany, has applied to the State Legislature for an appropriation of $100,000 to build underground sewers, etc., and $50,000 for changes in the sewage disposal plant, at Central Islip State Hospital.

NEW YORK.—The Beth Israel Hospital, 70 Jefferson St., will install a laboratory in the sixteen story, 175 x 200 ft. hospital, which it plans to build on Livingston Pl. between 16th and 17th Sts. Total estimated cost, $1,000,000. Louis Abramson, 220 5th Ave., engineer.

NIAGARA FALLS.—The Titanium Alloys Manufacturing Co., 2950 Sugar St., will build a two story, 50 x 50 ft. addition to its plant.

POUGHKEEPSIE.—Bids will soon be received by L. F. Pilcher, state architect, Capitol, Albany, for the construction of a filtration plant and reservoir for the Hudson River State Hospital, here. Estimated cost, $50,000.

RAY BROOK.—The State Hospital Commission, Albany, has applied to the State Legislature for an appropriation of $25,000 to install a new Imhoff system for the sewage disposal at the New York State Hospital for the Treatment of Incipient Tuberculosis.

SYRACUSE.—The Intercepting Sewer Board and the Board of Estimate and Apportionment plan to construct a modern sewage disposal plant at Lake View Point, complete Onondaga Creek improvement and immediate diversion of sewage from barge canal harbor to temporary clarification plant on salt sands.

UTICA.—The State Hospital Commission, Capitol, Albany, will build a two story, 44 x 60 ft. laboratory at the Utica State Hospital. Estimated cost, $50,000.

Ohio

OBERLIN—The Board of Education is having plans prepared by F. C. Warner, architect, 767 Hippodrome Annex, Cleveland, for a two story, 75 x 180 ft. high school building, including chemistry, botany and agricultural laboratories, etc. Total estimated cost, $225,000.

CLEVELAND.—The Board of Public Service, City Hall, will build a filtration plant at the foot of East 49th St., having a daily capacity of 160,000,000 gallons. Estimated cost, $3,500,000. F. H. Betz, 604 City Hall, architect.

CLEVELAND.—The Board of Public Welfare, City Hall, will build a four story addition to the City Hospital, consisting of laboratory, convalescing ward, etc. Total estimated cost, $300,000. Frederich H. Betz, 604 City Hall, architect and engineer.

CLEVELAND.—The Glass Coating Co., 1209 Rockefeller Building, has awarded the contract for the construction of a one story, 165 x 240 ft. glass factory at St. Clair Ave. and Nickel Plate R. R., to include a chemical laboratory, to Harold Ferguson, 66 Beersford Rd. Estimated cost, $80,000.

Oklahoma

DUNCAN.—The city will soon award the contract for the construction of a sewage disposal plant. Estimated cost, $50,000. J. L. Davis, city clerk, Benham Engineering Co., Colcord Building, Oklahoma City, engineer.

IDABEL.—The city is having preliminary plans prepared by the Benham Engineering Co., engineer, Colcord Building, Oklahoma City, for the construction of a complete sewerage system, including main and lateral sewers and a sewage disposal plant. T. J. Bookout, city clerk.

INOLA.—The Liberty Oil & Carbon Co. will build a refinery. Estimated cost, $250,000.

PICHER.—The King Brand Mining Co. of Picher, and Jefferson City, Mo., will open a zinc and lead mine in the Picher District and will soon be in the market for a 200-ton concentrating plant. Address D. M. Oberman, Jefferson City, Mo.

PICHER.—The Oklahoma Lead & Zinc Co. will move its mill from Commerce and erect same here. The company is in the market for boilers, engines, compressors and tables. T. F. Lennan, manager.

TAR RIVER.—The Alexander Mining Co. will move its mill from the Arkansas field and erect same at Tar River. The company is in the market for compressors, engines, rolls, pumps and screens. Estimated cost, $60,000. G. B. Ramsey, manager.

Pennsylvania

BRIGHTON.—The city plans to construct a garbage disposal plant. R. Winthrop Pratt, 716 Hippodrome Building, Cleveland, Ohio, engineer.

WOODLAWN.—The borough has had plans prepared for the construction of a sewage disposal plant. Estimated cost, $50,000. W. M. Anderson, borough engineer.

Tennessee

NEWPORT.—The Unaka Tanning Co. will rebuild its plant recently destroyed by fire. Loss between $300,000 and $500,000.

Texas

DAMON MOUND.—The Universal Sulphur Products Co., incorporated by W. C. Hardcastle, and H. T. Staiti, Chronicle Bldg., Houston, with a capital of $12,000,000, will develop a 7000 acre tract and install a plant for mining raw products, refining it and manufacturing sulphuric acid.

FT. WORTH.—The city is having preliminary surveys made for the construction of a sewage disposal plant. F. J. Von Zuben, city engineer.

HOUSTON.—The Clarendon Refining Co., Clarendon, Pa., has purchased the property of the Crown Oil & Refining Co. and will build a refinery, having a capacity of 5000 barrels. G. E. Colvin, president.

McKINNEY.—A. E. Boger, Dallas, will build a refinery. Estimated cost, $500,000.

RANGER.—Plans are being considered by the City Commissioners for the installation of a new sewerage system and sewage disposal plant.

Virginia

MONTEBELLO.—Richards & Co., Inc., has taken over the Irish Creek Tin Mines and plans to develop same, to include the installation of air drills and the usual equipment. Wiley S. Young, 200 Causeway St., Boston, Mass., treasurer.

NORFOLK.—The Hubbard Fertilizer Co., 802 Keyser Building, Baltimore, Md., has awarded the contract for the construction of a 150 x 192 ft. fertilizer plant at Money Point, near here. W. T. Gregory, 501 Law Building.

Wisconsin

MADISON.—The city plans to improve the sewage disposal plant. Estimated cost, $10,000. E. E. Parker, city engineer.

MILWAUKEE.—The National Oil Products Co., 220 Broadway, New York City, N. Y., has purchased a ten acre site at Keefe and Humboldt Aves., on which it will conduct a modern chemical plant. Estimated cost, $100,000.

WAUSAU.—The city plans to install a filtration plant and air lift system to have a capacity or 4,000,000 gallons; also two reservoirs having a capacity of 250,000,000 gallons. W. G. Kirchoffer, Madison, engineer.

Wyoming

ROCK RIVER.—The Midwest Refining Co. has purchased a site of thirty-eight acres here on which an oil refinery will be constructed.

British Columbia

MERRITT.—The Aberdeen Mines, Ltd., will build a copper mill in the spring. Estimated cost, $100,000. T. J. Corwin, manager.

VANCOUVER.—The International Food Products Co., Ltd., will build a vegetable oil plant to cost $20,000. Machinery costing $20,000 will be installed in same. Singer, Perlstein & Co., c/o the company, architect.

New Brunswick

NASHWAAK.—The Nashwaak Pulp & Paper Co. plans to construct a new mill. Estimated cost, $40,000. N. M. Jones, general manager.

Newfoundland

ST. JOHN'S.—Captain Storm will build a pulp and paper mill on the Terra Nova River. Estimated cost, $1,000,000.

ST. JOHN'S.—The Imperial Oil Co., 56 Church St., Toronto, Ont., will build an addition to its plant here. Estimated cost, $50,000.

Ontario

HAMILTON.—The City Council plans to reconstruct the sewerage system and install a modern sewage disposal plant. E. R. Gray, city engineer.

HAMILTON.—The Dominion Foundries & Steel Co., Ltd., will install a plate mill to roll 42-inch universal and 84-inch sheared plates, and will have a capacity of from 10,000 to 12,000 tons a month.

LINDSAY.—Plans are being considered by the city for the construction of a new sewage disposal plant.

PETERBOROUGH.—The Utilities Commission has purchased the old Carnegie property at the north end of the city and will use same for the construction of a filtration plant.

Saskatchewan

SHAUNAVON.—L. C. Robinson, Calof Building, 3rd Ave., will install a complete new vulcanizing plant and is in the market for machinery.

Coming Meetings and Events

THE AMERICAN CERAMIC SOCIETY will hold a meeting at Pittsburgh, Pa., Feb. 3, 4 and 5, jointly with the U. S. Potters' Association. Following are the professional divisions with their representative chairmen: White-ware and porcelain, Mr. C. L. Sebring; refractories, Mr. A. V. Bleininger; glass technology, Mr. C. H. Kerr; abrasives, Mr. R. C. Purdy; enameled metals, Mr. R. D. Landrum; Terra Cotta and Faience, Mr. F. B. Ortman; brick and tile, Mr. M. P. Blair. Other annual meetings held at the same time are the National Brick Manufacturers' Association, National Paving Brick Manufacturers' Association, National Building Brick Bureau and the National Clay Machinery Manufacturers' Association. There will be an opportunity to inspect the laboratories of the Bureau of Standards, Mellon Institute, University of Pittsburgh.

THE AMERICAN ELECTRO-PLATERS' SOCIETY, NEW YORK BRANCH, will have its 10th annual banquet at the Broadway Central Hotel, Saturday, Feb. 22, at 7:30 p. m.

THE AMERICAN INSTITUTE OF MINING ENGINEERS, which includes the Institute of Metals Division, will meet at the New York Headquarters, 29 West 39th St., Feb. 17 to 20 inclusive.

THE CANADIAN MINING INSTITUTE will hold its twenty-first annual meeting on March 5 to 7, 1919.

THE TECHNICAL ASSOCIATION OF THE PULP AND PAPER INDUSTRY will meet at the Waldorf-Astoria and the Hotel Astor, Feb. 3, 4, 5 and 6, 1919.

Industrial Notes

W. S. BARSTOW & Co. announces the completion of a potash recovery plant for the Ironton Portland Cement Co. The Cottrell system of electrical precipitation is used. It is expected that the product will amount to about 30,000 pounds of dust per day and as the raw material is unusually high in potash a large output of this mineral is expected.

E. I. DU PONT DE NEMOURS & Co., Wilmington, Del., has made application to the Federal Trade Commission for enemy patent licenses covering 148 dye patents.

THE AMERICAN PIPE BENDING MACHINE Co., with offices at 39 Pearl St., Boston, Mass., is about to open pipe-bending plants in all large cities throughout the country. The first plant is about ready for operation at Lowell, Mass. "Wonder" pipe benders, manufactured by this company, will be used at all plants. The company will make a specialty of furnishing bent pipe and make delivery of small orders on 48 hours' notice. Each plant will have facilities for turning out from 1000 to 3000 bends per day, and will be in charge of an expert pipe bender. The present company has been capitalized at $100,000, the old company is about to be re-organized with a capital of $1,000,000 to carry on this business.

THE ELECTRIC FURNACE Co., Alliance, Ohio, has closed a contract with the Standard Roller Bearing Co. of Philadelphia for 190 kw. continuous, automatic, heat-treating equipment. The set consists of one 150-kw. electric furnace for hardening and one 40-kw. electric heated oil-drawing bath. There is supplied in addition an oil-quench bath located between the furnace and the electric-heated, oil-drawing bath. Material, which consists of alloy steel balls and ball races, is automatically handled through the furnaces, quench, and drawing baths, in metal baskets.

THE DRAEGER OXYGEN APPARATUS CO., 309 Broadway, has changed its name to the American Atmos Corporation.

THE DETROIT RANGE BOILER & STEEL BARREL Co., Detroit, Mich., is a new company, consolidating the old Detroit Range Boiler Co. and the Toledo Steel Barrel Co. The new organization is capitalized at $1,000,000 and its officers are Edward W. Stoddard, president; Frederick G. Wacker, vice-president; D. B. Duffield, treasurer, and George A. Moore, secretary. At Detroit the company will manufacture the "Perfect" metal bilge barrel and at the Toledo plant they will make "Detroit" drums. There will be branch offices in Philadelphia, Chicago, St. Louis and San Francisco.

THE ASPROMET COMPANY of Pittsburgh, Pa., announces the opening of a sales office in the Schmulbach Building, Wheeling, W. Va., under the direction of Mr. E. A. Short.

THE HAUSER-STANDER TANK Co., Cincinnati, Ohio, has recently moved into enlarged and up-to-date quarters covering about three acres of ground.

THE FULLER-MACCULLOCH Co., Denver, Colo., are erecting in Denver a plant for the manufacture of potash salts, by a new electrochemical process, and in addition are producing phosphates and other like products. They desire catalogs and other literature relating to milling machinery, such as crushers, pulverizers, filters, dryers and evaporating machines.

THE QUIGLEY FURNACE SPECIALTIES Co. has opened a branch office in Providence, R. I., at 302 Turks Head Bldg., in charge of Mr. F. W. Reisman, who has been the Quigley Co.'s Eastern New England representative for hytempite (high-temperature fire brick cement) and insulating brick as well as the air transport system for distributing and burning powdered coal and other fuels.

THE MAYWOOD CHEMICAL WORKS, Maywood, N. J., is the name for the consolidation of the Schaefer Alkaloid Works, the Standard Essence Co. and the Thorium Chemical Co.

THE G. A. BURRELL Co., in cooperation with the R. H. Brownlee Laboratories, has installed at Pittsburgh, Pa., complete equipment for the laboratory and plant testing of chemical processes and especially natural gas, gasoline and petroleum products. It is prepared to handle all problems in connection with these latter substances. Col. G. A. Burrell recently left the Service, where he had charge of the research division of the Chemical Warfare Service. Prior to that time he was in consulting chemical engineering practice, following ten years in the U. S. Bureau of Mines in charge of gas investigations. Dr. R. H. Brownlee spent four years in the laboratories and plant of the Standard Oil Co.'s refinery at Whiting, Ind. Since that time he worked at the Mellon Institute on a gas fellowship, following which he became director of research and development for the Benedum-Trees interests in Pittsburgh, Pa.

THE WHEELER CONDENSER & ENGINEERING Co. of Carteret, N. J., announces that it has obtained from the Schutte & Koerting Co., of Philadelphia, through the Alien Property Custodian, the exclusive right to manufacture and sell steam jet air pumps under Patent No. 968,926 in connection with surface condensers, jet condensers, barometric condensers, vacuum pans and evaporating apparatus.

THE UNIVERSAL ENGINEERING CORPORATION, 1229 Calvert Building, Baltimore, Md., has been organized by John F. Dizu-

weit, William W. Varney, Raymond M. Glacken and Frederick E. Fisher. The company will conduct a general engineering business and research laboratory, and is especially well equipped to solve all problems in connection with electrochemical, metallurgical, mechanical and high-temperature engineering, also the handling of patents, foreign and domestic, investigation, appraisement, litigation, constructing and re-constructing of industrial plants, converting of breweries and distilleries into modern food products plants, etc.

THE LUDLUM STEEL CO., Watervliet, announces the following branches and branch managers: New England territory, Wheelock, Lovejoy & Co., Inc., Cambridge, Mass.; New York, Connecticut and New Jersey territory, Arthur A. Colebrook, 2 Rector St., New York City; Philadelphia territory, E. L. Milnor, 1517 Real Estate Trust Bldg., Philadelphia, Pa.; Railroads, S. T. Pearsons, 47 Terrill St., Rutland, Vt.; New York State, west and central, E. R. S. Reeder, Buffalo, N. Y.; Detroit territory, William A. Edwards, 2012 Dime Bank Bldg., Detroit, Mich.; Chicago territory, C. V. Luin, 928 Peoples Gas Bldg., Chicago, Ill.; Cincinnati territory, K. E. Porter, 816 Mercantile Bldg., Cincinnati, Ohio; Cleveland territory and Pittsburgh territory, V. S. Yarnall, 637 Guardian Bldg., Cleveland, Ohio.

THE PENARROYA MINING AND METALLURGICAL COMPANY of Paris has retained the American firm of Bradley, Bruff and LaBarthe to design a complete lead smelting and refining plant for erection at Penarroya, Spain. The plant will comprise crushing and sampling machinery, multiple hearth and Dwight and Lloyd roasting and sintering equipment, four large lead blast furnaces, one copper blast furnace, lead-copper matte converting plant, zinc desilverizing lead refinery and lead manufacturing machinery. The roasting and metallurgical furnaces will require pulverized coal.

THE UNITED STATES DEPARTMENT OF LABOR, working conditions service, has recently issued a memorandum showing the purposes and methods of industrial medical service in factories and large commercial organizations. Through the division of industrial hygiene and medicine, the working conditions service has laid out the program as follows:

To make studies of working conditions in their relation to health to determine hazardous processes and methods;

To formulate sanitary codes and regulations to meet health hazards in the various industries;

To formulate standards of medical practice in industries, to cooperate in the betterment of medical service in industries and industrial centers;

To determine standards of physiological requirements of various occupations;

To determine methods for proper placement of workers;

To secure statistical data of industrial morbidity;

To promote facilities for the education and training of physicians and sanitarians for industries;

To assist industries in obtaining physicians and other technicians for industrial service;

To disseminate information concerning measures necessary to safeguard workers against industrial health hazards, and to secure cooperation of all elements, governmental and private, in furtherance of the industrial health program.

The working conditions service particularly calls attention to its register of industrial physicians, which will aid manufacturers in getting in touch with physicians especially qualified for industrial service.

HAMILTON & HANSELL, INC., 13 Park Row, New York, has formally opened a steel warehouse at 141 Raymond Street, Brooklyn, which has been in existence since July, 1918, carrying a full line of tool steel and special alloy steels, in rounds, squares, octagons and sheets. Mr. C. U. Ackerlind is manager of the steel department.

THE SLIGO IRON & STEEL CO., Connellsville, Pa., makers of iron and steel bars, expects to make additions to its plants to increase output to 5000 tons monthly.

Manufacturers' Catalogs

THE INDUSTRIAL FILTRATION CORPORATION, 115 Broadway, New York City, has just received from the press a booklet describing andillustrating open tank filters, rotary filters, rotary clarifiers or thickeners, rotary hopper dewaterers and special filtration apparatus.

THE HYGEIA RESPIRATOR CO., 32 Monroe St., Passaic, N. J. A pamphlet describing the Diamond-Mask model "C" respirator.

E. H. SARGENT & CO., Chicago, Ill., calls attention in a pamphlet to Sargent's electric drying oven with automatic temperature control, giving directions for operating.

THE P. H. AND F. M. ROOTS CO., Connersville, Ind., calls attention to Catalog 68 on its rotary blowers. This is an attractive 48-page catalog which describes and illustrates many different types of blowers.

THE UNION THERMOMETER COMPANY, INC., 1301 Boston Road, New York City, has issued a special descriptive folder on chemical or laboratory thermometers, including the length of scale, range of scale and price per piece and per dozen.

THE GREEN ENGINEERING CO., East Chicago, Ind., has issued a 16-page booklet on Green materials transfer and storage hopper which is finding many uses in the chemical and allied fields for storing such materials as granular fullers earth, gilsonite, kieselguhr, ferrosilicon, bauxite, etc.

THE EDW. R. LADEW CO., INC., Glen Cover, N. Y., has issued an attractive catalog entitled "Ladew Leather Belting." It has 108 pages and illustrations and descriptive matter explaining step by step the operations involved to make the raw material into the finished product. A discussion is also given of belt engineering and belting economies.

MILLIKEN BROTHERS MFG. CO., INC. Woolworth Bldg., New York, call attention to an attractive 24-page booklet entitled "Space and Speed in Steel Buildings" descriptive of the standardizing truss unit system of building construction. Many interesting illustrations are given.

RAYMOND BROS. IMPACT PULVERIZER CO., Chicago, Ill.: Catalog No. 13 is a very attractive 64-page booklet on grinding, pulverizing and separating machinery. Illustrations and descriptive matter explain roller mills and pulverizers equipped with air separation for grinding all kinds of materials to powdered form. This catalog not only covers Raymond equipment but it gives some very good general ideas regarding pulverizing problems.

JOHN SIMMONS CO., 110 Centre Street, New York, calls attention to a 12-page booklet on the Leinert automatic gravity scales, for the automatic accurate weighing of liquids such as water, oil, sugar-juice spirits, petroleum, brine, acids, chemicals, etc. A description of the different uses for this scale, together with illustrations, is given.

THE RUTH COMPANY, Denver, Colo., describes and illustrates the Ruth flotation machine in a 12-page booklet. A copy can be had on request.

THE LINK-BELT COMPANY, Chicago, Ill., has just received from the press Book No. 353, "Economical Handling of Coal and Ashes and Reserve Coal Storage." By Henry J. Edsall. The booklet contains 52 pages of descriptive matter together with illustrations which are reprinted from a series of articles in *Steam* during 1917-1918. The same company also issues Book No. 333 "Link-Belt Equipment for the Handling and Preparation of Coal at the Mines." This attractive catalog contains 88 pages and illustrates coal tipples, conveyors, washeries and other equipment used at the mines.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., is distributing a novel two-page envelope folder which illustrates and enumerates the advantages of the C-H 91-16 starting switch for alternating current squirrel cage motors.

THE STAR BRASS WORKS, Chicago, Ill., has just received from the press Bulletin No. 4 pertaining to Spray cooling equipment as adapted for the re-cooling of condensing water for power and industrial plants.

THE FOXBORO CO., INC., Foxboro, Mass., calls attention to Bulletin 115, dated December, 1918, on power plant instruments which are used to reduce boiler-room expenses. This is an 8-page booklet, illustrated, which should be helpful to engineers who have not the time to look through the large bulletins issued by this company.

THE STEERE ENGINEERING CO., Detroit, Mich.: Bulletin No. 35 entitled "Tar Cameras for Colorimetric Tar Determination." This is an attractive 12-page booklet, well illustrated and supplemented by a colorimetric chart.

THE JOHN F. BYERS MACHINE CO., Ravenna, Ohio, has just received from the press Bulletin 1015 describing Model "9" autocrane. This 24-page catalog shows the various uses in many fields for the autocrane.

THE WALTER A. ZELNICKER SUPPLY CO., St. Louis, Mo., calls attention to Bulletin No. 250, which lists and illustrates rails, locomotives, cars, cranes, shovels, pipe, machinery, tanks, steel piling, power plant equipment, machine tools, wire rope, hoists and contractors' equipment. This bulletin is free to the trade.

THE GRISCOM-RUSSELL CO., 90 West St., New York: Bulletin No. 901 describes and illustrates the Multiwhirl Cooler, one of the uses of which is the removal of heat of waste liquors from chemical plants.

THE LAKEWOOD ENGINEERING CO., Cleveland, Ohio, sends as a New Year's greeting a very attractive booklet entitled "The Road to Peace," which is exceedingly interesting. It has 42 pages 10¾ in. by 14¼ in., printed in two colors and is profusely illustrated. Pictures are given of portable track, switches, and equipment being loaded onto a steamer for service overseas, military portable track piled in a French yard awaiting engineer requisition, and many others. One of especial interest is entitled "Blocking Off the Hun Advance Before the Second Battle of the Marne," which was snapped by a camera man with the American Expeditionary Forces and which shows a mine blowing up a bridge carrying Lakewood track.

New Publications

SOUTH DAKOTA SCHOOL OF MINES, Department of Geology and Chemistry, Rapid City, South Dakota, Bulletin No. 12 entitled "The Occurrence, Chemistry and Uses of Tungsten," with special reference to the Black Hills of South Dakota, by J. J. Runner and M. L. Hartman, including a bibliography of tungsten by M. L. Hartman, dated Sept., 1918.

THE FEDERAL BOARD FOR VOCATIONAL EDUCATION has issued a series of Opportunity Monographs. Vocational Rehabilitation Series, No. 5 "Army Occupations as Preparation for Civilian Employment"; No. 7 "The Metal Trades"; No. 8 "Factory Woodworking Trades"; No. 10 "Forestry Pursuits"; No. 11 "Automobile Maintenance and Service"; No. 12 "Employment Management" and No. 17 "The Practice of Medicine as a Vocation." These pamphlets are gotten out to aid the disabled soldiers, sailors and marines in choosing a vocation.

NEW BUREAU OF STANDARDS PUBLICATIONS: Tech. Paper No. 117 "Toluol Recovery" by R. S. McBride, C. E. Reinicker and W. A. Dunkley; Circular No. 3 "Design and Test of Standards of Mass." This third edition dated Dec. 23, 1918, supersedes the second edition entitled "Verification of Standards of Mass" issued Jan. 10, 1907.

NEW BUREAU OF MINES PUBLICATIONS: Bull. 154: Mining and Milling of Lead and Zinc Ores in the Missouri-Kansas-Oklahoma Zinc District. By Clarence A. Wright; Bull. 163: Methods of Shutting Off Water in Oil and Gas Wells. By F. B. Tough: Bull. 170: Extinguishing and Preventing Oil and Gas Fires. By C. P. Bowie; Tech. Paper 152: The Inflammability of Aluminium Dust. By Alan Leighton; Tech. Paper 171: Method of Least Squares Applied to Estimating Errors in Coal Analysis. By J. D. Davis and J. G. Fairchild; Tech. Paper 198: Sulphur Dioxide Method for Determining Copper Minerals in Partly Oxidized Ores. By Charles E. Van Barneveld and Edmund S. Leaver; Tech. Paper 200: Colloids and Flotation. By F. G. Moses; War Minerals Investigations Series No. 3 dated Dec., 1918, entitled "Preparation of Crucible Graphite" by Geo. D. Dub; Bull 161: Law Serial 13 California Mining Statutes Annotated. By J. W. Thompson, including all California mining laws.

NEW UNITED STATES GEOLOGICAL SURVEY PUBLICATIONS: II:36, Stone in 1916. By G. F. Loughlin. (Mineral Resources of the U. S., 1916, Part II, pages 993-1087), published Nov. 25, 1918; II:18, Asphalt. Related Bitumens and Bituminous Rock in 1917. By John D. Northrup. (Mineral Resources of the U. S., 1917, Part II, pages 232-251), published Oct. 22, 1918; II:22. Fluorspar and Cryolite in 1917. By Ernest F. Burchard. (Mineral Resources of the U. S., 1917, Part II, pages 293,304), published Nov. 20, 1918; I:9. Gold, Silver, Copper and Lead in Alaska in 1917, Mines Report. By G. C. Martin. (Mineral Resources of the U. S., 1917, Part I, pages 131-145), published Nov. 21, 1918.

Power Data for Electrolytic Zinc

By G. H. Clevenger and F. S. Mulock

THE accompanying straight line diagram shows graphically the relationships between the principal electrical data involved in the production of electrolytic zinc. It will be noted that each vertical line is subdivided into a logarithmic scale. The position and scale of the heavy lines A, C, E and IJ are first arbitrarily laid off.

The position and scale of line B, which represents the product of A, C and a constant, is then determined from the arbitrary scales on lines A and C. As line A represents ampere-hour efficiency and line C current in amperes, their product, when multiplied by time and the electro-chemical equivalent of zinc, will give the weight of zinc deposited for that time. Here the constant used was such that the scale of line B represents pounds of zinc per 24-hour day.

Similarly, the product of line C, representing current in amperes, and line E, representing voltage, is given on line D, which represents power in kilowatts.

Line D, representing kilowatts, multiplied by 24, gives kilowatt-hours per day. This product divided by line B, representing pounds of zinc per day, gives kilowatt-hours per pound of zinc, which is represented by scale F on line FG.

Using the theoretical decomposition voltage of the electrolyte and the electrochemical equivalent of zinc, it is possible to determine the theoretical kilowatt-hours required per pound of zinc. This value divided by the actual number of kilowatt-hours per pound of zinc (as found on scale F) gives the power efficiency. Scale G gives the power efficiency for a zinc sulphate electrolyte.

Line IJ gives the cost of power both in cents per kilowatt-hour and in dollars per kilowatt-year. From scale J of line IJ and scale F of line FG is determined the line H, which represents the cost of power in cents per pound of zinc.

The following problem will illustrate the use of the diagram:

Given: 1. Current, 5000 amperes. 2. Ampere-hour efficiency, 90 per cent. 3. Voltage, 3 volts. 4. Cost of power, $20 per kilowatt-year.

To find: 1. Pounds of zinc deposited per day. 2. Power in kilowatts. 3. Kilowatt-hours per pound of zinc. 4. Cost of power in cents per pound. 5. Power efficiency.

1. Place a straight edge on 90 of the A scale and 5000 of the C scale. Read pounds of zinc per day (291) at point where straight edge intersects the B scale.

2. Set at 5000 on scale C, and 3 on E, and read power (15 kw.) on D.

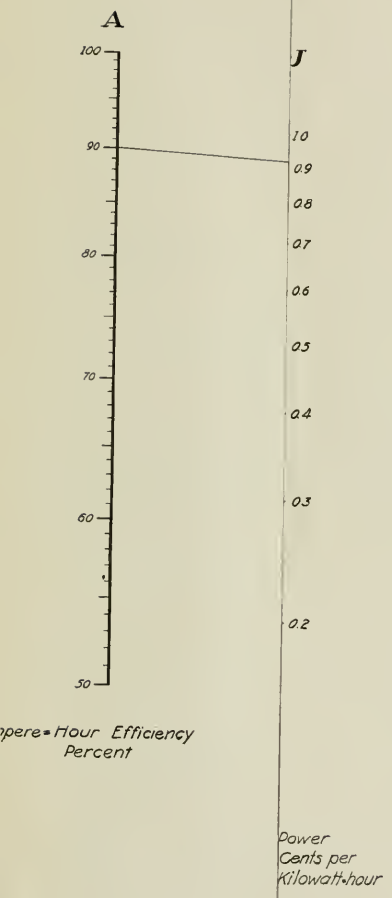
3. Set at points determined in 1 and 2, i.e., 291 on scale B and 15 on scale D; read kw.-hr. per lb. of zinc (1.24) on scale F.

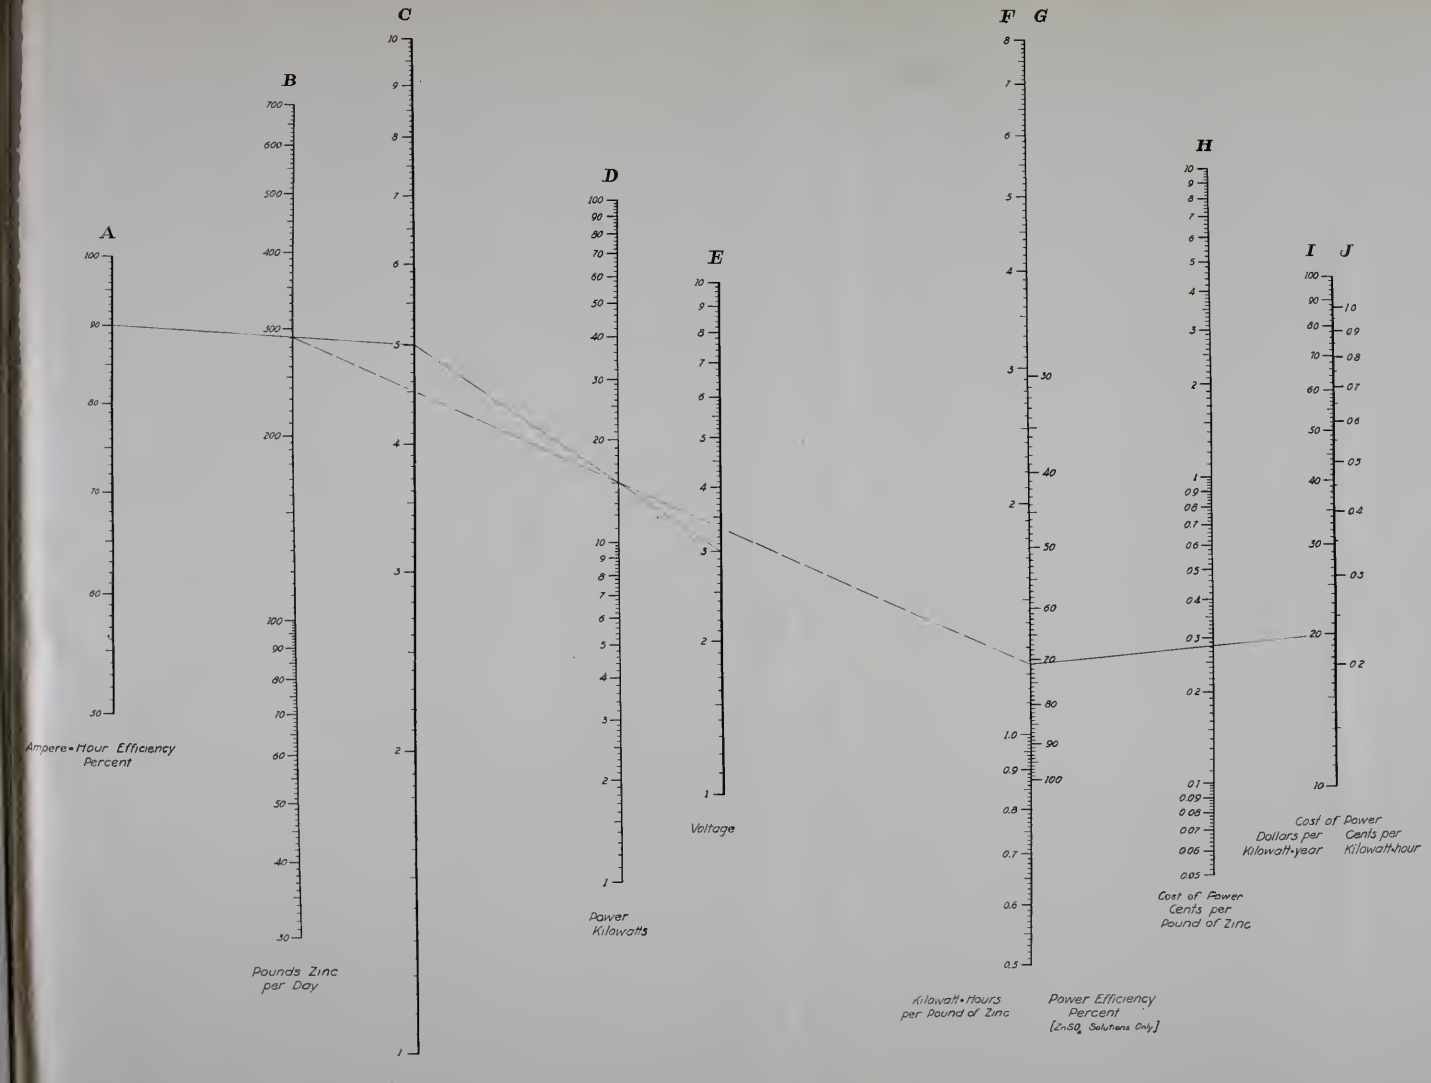
4. Set at 1.24 on scale F and 20 on scale I, and read the cost of power per pound of zinc (0.283 cents).

5. With the same setting as in 3, if the electrolyte is zinc sulphate, read the power efficiency (71 per cent) on scale G. (This scale cannot be used for electrolytes other than zinc sulphate.)

Note: The voltage to be used on scale E is the voltage per cell. When cells are connected in series, divide the total voltage by the number of cells. The output of each cell may be ascertained by using the average current per cell on scale C. The total output of the plant may then be found by multiplying this result by the number of cells in use.

Similar straight line diagrams can be prepared showing the relationship between the electrical data involved in the electrodeposition of the other metals.





Power Data for Electrolytic Zinc

By G. H. Clevenger and F. S. Mulock

THE accompanying straight line diagram shows graphically the relationships between the principal electrical data involved in the production of electrolytic zinc. It will be noted that each vertical line is subdivided into a logarithmic scale. The position and scale of the heavy lines A, C, E and IJ are first arbitrarily laid off.

A New View of Gas Warfare

WHEN the Germans introduced poison gas as a means of attaining their military ends they were universally condemned for committing a fiendish act; and military critics referred to it as a reversion to the use of the stink-pot by the Chinese. It was, indeed, a detestable method of warfare that had not occurred to the Allies; or if it had occurred to them it was rejected as abhorrent. But in order to fight the devil with fire the Allied and American armies began extended research in the manufacture of poison gases and protective masks, and ultimately excelled their enemies in this mode of warfare, just as they did in all others. Indeed the Germans were being rapidly gassed into submission and would have been given still larger doses but for their sudden capitulation.

It is likely that our first unfavorable impressions of gas warfare have become fixed in our minds, so that a defense of the practice will be more or less shocking to the layman. From a military aspect, however, gas has such favorable possibilities that it is regarded in some quarters as one of the most effective and humane weapons of the future. Our readers will be especially interested in an article on another page giving the views of Brigadier General Amos A. Fries, who was recently interviewed by a member of our editorial staff. General Fries was in charge of the Chemical Warfare Service in France, and speaks from experience. He finds gas a weapon of great possibilities; effective against an unprepared foe, but of little or no avail where ample protection is provided. Less frightful in maiming and wounding men, it is more humane than shrapnel and high-explosive shells; and there is a lower death rate from gas casualties than from those caused by gunfire. As a means of rendering mobs tractable, lachrymator gases may find useful application in civil life. On the whole there seems to be a possibility of developing this unhappy offspring of iniquity into something useful, and we commend a careful reading of General Fries' views.

Dislocation of the Copper Industry

ARGUING, at this late date, the wisdom in the continuance of copper production at a maximum rate after the signing of the armistice had absolutely killed the market both for governmental and individual account is hardly of value. The large producers and the Government must have seriously misjudged the American and the world market conditions in order to have piled up a billion pounds of high-cost copper, finished and in process—the present visible stock,

according to reliable estimates. November and December passed without a single large sale. Organizing to control export trade, the copper producers formed a *de facto* trust and in January set the export price at 23 cents—purely a figure of hope, since foreign companies could readily cover current needs by purchasing the reserve stocks held by their Governments at a materially lower figure. Nothing prevented the American producers from almost unanimously asking 23 cents for local delivery; on the other hand, nothing forced American consumers into buying at that price. In the face of this stalemate, curtailment became the order of the day, and at present the output is probably at the rate of 100,000,000 pounds per month.

A reduction in output to about 60 per cent normal naturally laid off a number of men in the mines and mills. Avoidance of serious unemployment was perhaps the sole justification of previously maintaining large over-production. This surplus labor added to the ranks of returning soldiers created such a serious outlook that Secretary of Labor Wilson held a conference with labor union representatives from Montana, Utah and Arizona early in February to solve if possible the riddle. These meetings listened to a statistical statement of the present copper market, an address from John D. Ryan, explaining the financial position of the producing corporations, and various schemes from the workmen designed to maintain war-time wages and employment.

This seems impossible of attainment. Sales in quantity began to occur during the first week in February at a fraction over 18 cents. Immediately thereafter the large producing companies posted notices that the wages would again be determined by a sliding scale, based on the market price of the metal, a system largely used in the industry and in many camps sanctioned by contracts between companies and unions. In the absence of any market, wages for February will be figured either on a basis of 20-cent January copper or on the daily current price (depending upon custom); either plan will involve a horizontal wage reduction of from 75 cents to $1 per day. Even at this, the daily rates are 50 cents or more higher than existing agreements call for, since the wages recently paid were accepted as the scale for 26-cent copper, while as a matter of fact, it more nearly approximates the 30-cent scale, maintained without reduction by agreement with the War Industries Board. The Anaconda Copper Mining Company also announced that no further decrease in wages is anticipated, should the market fall below 17 cents.

The unfortunate feature of the labor situation in the copper industry is that the miners decline to accept the wage reduction which accompanies the decreased price for the metal. The sliding wage-scale based on metal prices is always acceptable to the miner as long as prices are rising, but his memory is rather short when the time comes for him to perform his part of the contract and accept the wage reduction. The consequence is that mining and milling operations are practically suspended in the Butte district owing to a strike fomented by the notorious and vicious I. W. W. The fear has been expressed that the dissension will spread throughout the other Western copper districts. We can imagine that the companies will be glad of an excuse to close their properties in view of the present high cost of production and the prospect of a falling market. The miners have nothing to gain except through a straightforward and generous acceptance of their share of the loss which the sudden ending of the war brought to the industry.

Proposed Improvements in American Patent Procedure

WHEN the Commissioner of Patents in 1917, with the approval of the Secretary of the Interior, requested the National Research Council to investigate our Patent Office and its procedure, a step was taken which we are so bold as to believe will result in remedying some of the imperfections on our patent system. These have long been apparent to those who have much to do with the Patent Office. Considering the vital part played by this institution in our national life, it is important that it be made as efficient and effective as possible. No organization is better qualified than the National Research Council to appreciate the excellence or deficiency of the Patent Office, and the recommendations of a committee from that body should carry weight with Congress when it is asked to pass the necessary bills.

In a report of the patent committee to the Council it is recommended that a simple program of four features be adopted, and that the necessary legislation be obtained from Congress to put the proposals into practice. The first proposal concerns a single Court of Patent Appeals to supersede the nine Circuit Courts of Appeals, as far as patent cases are concerned. The second recommends that the Patent Office be made a separate institution, independent of the Interior or any other department of the Government. The third relates to substantial increases in the force employed in the Patent Office and in the salaries paid. The fourth seeks to make it possible for a patentee to obtain not only an injunction against an infringer in a case where a patent is adjudged valid, but also a reasonable royalty or other form of general damages.

There is no doubt that some step should be taken to remedy the farcical situation which can and does now arise in the adjudication of patents by our Circuit Courts of Appeals. As matters stand at present it is possible for the same case to be decided differently in two different circuits. Obviously a single agent is much preferable to nine having equal authority. But the question has been raised previously as to the wisdom of adjudicating patents *after* they have been granted instead of *before* they are issued. Those to whom letters patent have proved an expensive form of introduction to the Supreme Court have some ground for feeling that a court of experts weighing the claims of contestants before a patent is issued would be a quieting factor in our industrial life. Perhaps the committee of the National Research Council has considered this alternative and has concluded that a Court of Patent Appeals is preferable. Certainly it will be much preferable to our present courts for patent cases.

The movement to make the Patent Office a separate institution is believed to be in the interest of better administration. At present the Secretary of the In-

terior is at best a figurehead in its affairs, and the Patent Office suffers by irrelevant comparisons with other bureaus in the Department of the Interior. Only the highest approval can be given to the recommendation that the force of examiners and clerks be increased and that their salaries be raised to figures comporting with their ability. It is a reflection on the country that the salaries of examiners have been increased only 10 per cent since they were fixed in 1848! As to compensation for infringement of patents, we are in accord with the committee in seeking to secure a financial return to an inventor whose rights are violated.

Injunctions buy no bread for the winner, nor do they constitute a serious punishment to the loser. Money compensation would be more tangible justice to the inventor and probably a stronger deterrent against deliberate infringement.

Restoring the Dollar's Value

TO RE-ESTABLISH business on a sound basis, indeed to re-establish industrial activity at all, it is necessary that the old-time value of the dollar be largely restored. It is impossible to change suddenly the value of the dollar and then have everything move substantially as before. No real prosperity can occur. The proper conception of prosperity is that of making progress, of obtaining new things. A state of society is conceivable in which men would merely produce the same quantity of material year in and year out, consume the same quantity, and be contented. They would merely be doing the same things over and over again. To conceive such a condition requires much imagination, for the concept is not in keeping with our traditions or habits of thought. Often we say that the luxuries of one day become the necessities of the next, which of course means that progress is essential to contentment, for while one might get along without luxuries and be somewhat contented he would certainly not be contented when those articles had become necessities.

Prosperity, then, not merely being busy but making progress, means development, doing new things, making new products. All this involves the providing of additional facilities, for which capital must be expended, changing from liquid to fixed form. More or less the capital invested in any year comes into competition with the capital that was invested in previous years. If the capital already invested was at a certain scale of values, of prices for commodities and labor involved in making the investment, and the new capital must be invested with a much higher scale of values obtaining, the competition places the new capital at a great disadvantage.

At a time like this capital shrinks from seeking investment in works of construction, which are necessary to our prosperity and advancement, both because it must come in competition with capital already invested to better advantage and because it faces the menace of a future time when it may be possible to invest capital to better advantage, through lower prices then obtaining for labor and materials.

If the investments now existing in the country had appreciated in intrinsic value, keeping pace with the reduced purchasing power of the dollar, the condition might not be unsatisfactory. Things might possibly work out fairly well. This, however, is not the case by any means. The wealth of the country is not estimated at much more than before the war-time inflation occurred. The plight of most public service corporations is a practical example. If, assuming that the purchasing power of the dollar has been cut in half, the value of their properties, measured in dollars, had doubled, they would obviously be in very happy position; but the actual fact is that through the decreased purchasing power of the dollar their cost of operation is increased and the intrinsic value of the properties is decreased rather than increased. High wages cannot maintain high commodity values, nor can high commodity values maintain high wages. The value of existing properties, buildings, bridges, power plants, factories and other investments can, however, exercise an influence to pull down investment costs when they are so high that capital does not seek outlet through such investments. Inevitably this pulling down process is going to occur, and it is unwise not to face the fact squarely. If through lack of understanding people do attempt to resume full-time activity without the necessary adjustments having been made, there will simply be so much the more to adjust at some later time.

No one, of course, can intelligently argue that prewar conditions and prices must return, or ever will return in full. To an extent conditions have changed. The position of labor has been altered by the war and former conditions will never be fully restored. The common laborer wants more, and will get more, for his labor in proportion to the pay of the more highly skilled man.

The war has shown that it does not require so long for a man to become skilled after all, and the fact that a man's work is skilled and therefore interesting is going to be taken as part of his reward for doing the work. Furthermore, the change that has been working for centuries must be regarded as having been in operation, double time, during the period of the war. The value of the dollar decreases from century to century. In 1897 and 1898 very low prices obtained in the United States. In succeeding years prices advanced rather steadily and there were those who looked for them to return eventually to the old level. That was a mistaken apprehension. Whether it is the increasing volume of money and credit, according to the quantitative theory, or a combination of influences, need not be discussed. It may be accepted as reasonably certain that with various fluctuations the value of the unit of money tends to decrease. If the price of a given commodity declines, it is merely a temporary fluctuation, an adjustment of a too great advance previously, or a decrease in the cost of producing the article.

Thus commodity prices and wage rates cannot be expected to be restored to the plane which they occupied before war was declared, but there must be a very considerable readjustment in that direction before industry can go ahead, development be undertaken and the people become really prosperous.

Western Chemical and Metallurgical Field

Secondary Mining Schools in Nevada

THE fifth session of the prospector's short course was held at the Mackay School of Mines at Reno, Nevada, during January. The majority of those attending were miners and mining men, although there has always been a considerable number of other trades or professions who are interested in prospecting as a side issue. Such courses offer a good opportunity for one to brush up his knowledge of prospecting, assaying, mineralogy and geology.

While similar courses have been instituted in several Western mining schools, the Mackay school at Reno is unique in instituting a system of secondary mining education for miners and mill-men, which includes a traveling mining school, which moves from camp to camp, visiting any localities which obtained an advance registration of at least twenty men, and continuing for one or two periods of three months as the attendance warranted.

Beginning with one school, operated as an extension department of the University of Nevada, the system has grown until it now consists of five distinct schools. Four of these are permanently located at Virginia City, Tonopah, Goldfield, and Ely, while the fifth is a traveling school at present in session at McGill. The only requirement for entrance into these schools is the ability to talk and read English, and while the instruction is elementary and practical in character thirty-seven different courses are offered and may be combined into various groupings sufficient to better the training in many vocations. The regular class work consists of two hours daily, which is as much as can be expected from men who are working continually at their trade. Instruction is given at two different two-hour periods to accommodate men working on different shifts, but the laboratories are open at all times during the week.

It is evident that in these schools no attempt can be made to train mining engineers and metallurgists. The object rather is to acquaint the student with some of the technical theory underlying his everyday work, thus making him a more intelligent and efficient workman and citizen. The young men who have a common school education and who do well in these secondary schools are offered every encouragement to go to the Mackay School of Mines for engineering training.

1918 Mineral Production in British Columbia

BROADLY speaking, the industrial conditions during the past year have not been unsatisfactory; and while it is not anticipated that the production will equal the record of 1916, it should compare very favorably with that of 1917. According to the January Bulletin of the Canadian Mining Institute, the production of coal for the nine months of 1918 showed an increase of 255,188 tons as compared with the output for the corresponding period of 1917. Production during the last quarter of the year has been well maintained despite the fact that operations, especially in the Crowsnest area, have been impeded by strikes and by the recent epidemic of influenza. So far as copper is concerned the total output for nine months of 1918, according to the official records, was 45,518,223 lb. as compared with a total production during 1917 of 59,700,565 lb. The value of the silver produced owing to the advance in the market price of this metal is likely to show an increase over last year; the lead and zinc output will probably be less than last year. The suspension of operations at the Rossland mines for a considerable period during the year will inevitably affect the showing as regards the province's gold production, but this has been more than offset by the entry of the Surf Inlet mine into the productive class. Preliminary figures follow:

Placer gold	$300,000
Lode gold	$3,627,500
Copper, pounds	62,000,000
Silver, ounces	2,460,000
Lead, pounds	20,500,000
Zinc, pounds	23,055,000

Manufacture of Pure Stick Caustic Potash

AMONG the many chemical products obtained exclusively from Germany before the war is caustic potash in the form of pure white sticks, having a content of 85 per cent or more of KOH and designated as the U. S. P. quality. The chemical literature is lacking in description of processes for making this material, especially from the grades of raw material available in this country during the past two years. In establishing a plant having a capacity for producing this material of 1000 lb. per day the C. F. Burgess Laboratories claim to have developed a strictly American process for producing a U. S. P. grade of caustic from American raw materials.

The raw materials employed are crude caustic from wood ashes and potash derived from the alunite process. The white sticks as marketed are about 10 cm. in length and weigh approximately 10 g. While the tonnage demanded for this product is small, it is nevertheless important for laboratory use, in gas analysis, in pharmaceutical preparations and in various chemical products such as special shaving soaps and the like.

Penn-Wyoming Copper Co. Sold

WE HAVE been advised that the entire assets of the Penn-Wyoming Copper Co., Encampment, Wyoming, owner of the Saratoga & Encampment Railroad, the Ferris Haggerty and Doane-Rambler mines at that place, have been purchased by the Morse Bros. Machinery & Supply Co. of Denver, Colo.

The various subsidiary companies purchased and their respective bond issues follow:

Ferris Haggerty Copper Mining Co	$1,000,000
Battle Lake Tunnel Site Mining Co	750,000
Saratoga & Encampment Railroad Co	750,000
Encampment Smelting Co	500,000
Encampment Tramway Co	350,000
Encampment Pipe Line Ditch Co	100,000
Emerson Electric Light Co	50,000
Encampment Water Works Co	50,000
Carbondale Coal Co	20,000
North American Mercantile Co	22,000
Encampment Town Lot & Land Co	8,000
Total bond issues	$3,600,000

The stock of the Penn-Wyoming Copper Co. was $10,000,000. This company was the successor of the North American Copper Co., the promotion of WILLIS GEORGE EMERSON, who recently died in Los Angeles, the Penn-Wyoming company taking over the property in 1904 and operating it under the most unfortunate conditions of fire losses and financing of the railroad until 1907, when it was closed. Numerous attempts were made to reor-

ganize and resume operation. Company dissension arose during the efforts to reorganize, a receiver was appointed and litigation commenced which only ended in the Court of Appeals. The sale of the property to the bondholders' protective committee and the purchase by the Morse Bros. Machinery & Supply Co. from that committee brings the history to date of a mine with a record of having produced more than 10,000,000 lb. of copper since its discovery in 1898 by ED HAGGERTY.

The records of the Penn-Wyoming Copper Co. show a production of 6,414,011 lb. of copper from 59,000 tons of ore mined. From 1904 until operation ceased in 1907 the plants were operated a total of 372 days. In 1906 the concentration and power plant was destroyed by fire but was rebuilt and put in operation the latter part of March, 1907, and operated until May 10 of that year, when the smelter and tramway terminal were destroyed by fire. These plants were rebuilt and began operation in May, 1908, and were operated until closed down in October of that year owing to financial difficulties occurring through the building of the Saratoga & Encampment Railroad, which connected the smelter at Encampment with Wolcott, Wyoming, on the main line of the Union Pacific Railroad. Previously all of the coke and supplies were hauled in and the finished product was hauled out to Wolcott, the nearest railroad point 47 miles distant.

The tramway connecting the Ferris Haggerty mine with the smelting works at Encampment is one of the longest aërial tramways in the world, its length being 16⅔ miles. It is operated in three sections, with a power plant at each section. There are 304 towers, tension and anchor stations, 884 buckets and 63 miles of wire rope. The track cables are 1¼ in. and 1 in. and the traction cables ⅞ and ¾ in. The cost of operation during the period was $0.9347 per ton of ore handled.

Twelve cars of ore shipped from the Doane-Rambler mine in 1901 averaged 40.7 per cent copper. and exhibits of ore from this mine at the St. Louis Exposition showed values of 900 lb., or 45 per cent, copper to the ton, these ores being bornite and chalcocite. This mine was bought to supplement the production of the Ferris Haggerty and has been developed to a depth of 665 ft. No ore has been taken out from the lower levels.

The Saratoga & Encampment Railroad runs directly south from Wolcott to Encampment, which is at the foot of the Continental Divide, at one of the lowest passes in the range. A survey has been made to connect this line with the Moffat Road at Steamboat Springs, a distance of sixty miles on a 2 per cent grade and a maximum altitude of 8500 feet.

The geological features of this district, many of which are interesting, are fully described in Professional Paper No. 25 by A. C. SPENCER of the Geological Survey, published in 1904.

An effort will be made by the purchasers to prove the value of the mines and have them operated if investigation will warrant the expenditures necessary. The smelter and concentrating plants at Encampment will be dismantled and the material sold, as concentration mills will be built at the mines and the concentrates transported to Encampment. Millsites and water rights are available at both the Ferris Haggerty and the Doane-Rambler mines.

California Mineral Production in 1918.

FLETCHER HAMILTON, the California State Mineralogist, has issued a preliminary statement of the mineral production of California which shows a wider variety of chemically valuable minerals than almost any other state in the Union and of a total value exceeded only by the large coal and iron producing states of the East. Gold decreased nearly $3,000,000 in value, while petroleum increased 5,000,000 barrels in quantity. Quicksilver dropped off about 2000 flasks, while manganese ores nearly doubled. Magnesite, however, dropped to 40 per cent of the previous year's total on account of the competition of the cheaper, iron-bearing magnesite from the state of Washington.

The estimated quantities and values for 1918 are:

Gold	$17,250,000
Silver (1,500,000 oz.)	1,450,000
Tungsten concentrates (2,300 tons)	3,000,000
Copper (49,000,000 lb.)	12,000,000
Lead (15,000,000 lb.)	1,100,000
Zinc (4,500,000 lb.)	375,000
Quicksilver (22,000 flasks)	2,310,000
Antimony, iron, molybdenum, platinum	90,000
Petroleum (100,000,000 bbl.)	123,000,000
Chromite (52,000 tons)	2,000,000
Manganese ores (25,000 tons)	1,125,000
Magnesite (90,000 tons)	900,000
Natural gas	3,000,000
Brick, cement, building stone, crushed rock, etc.	10,000,000
Miscellaneous "industrial" minerals	1,500,000
Salines (including borax, soda, salt, potash)	12,000,000
Total	$191,100,000

Company Reports.

Tomboy Gold Mines Co.—The annual report of this company for the year ended June 30 has just been issued. It shows that 151,000 tons of ore were milled at a cost of 70 cents per ton, yielding bullion worth $306,000 and concentrates worth $662,000 at a cost of 63 cents per ton. Tailings to the amount of 129,000 tons were cyanided at a cost of $1.08 per ton, yielding bullion worth $168,000. A marked shortage and inefficiency of labor has increased costs materially, and caused a reduction of ore reserves. Continuous tests were carried out from February to July with milling ore, so as to establish a reliable comparison between flotation and the present methods of treatment. The results confirmed the advantage of the flotation process, and it will make available large tonnages of developed low grade ore on the property. However, under the present condition of the labor and materials market, installation will be postponed.

The Coniagas Mines, Ltd.—The report for the year ended Oct. 31, 1918, shows that the mine at Cobalt and the smelter at Thorold, Ontario, have been operating continually. The tonnage milled was 68,597, or an average of 3.38 tons per stamp-day. From this ore was shipped 530 tons of high-grade concentrate containing 1164 ounces per ton, and 867 tons of slime concentrates containing 245 ounces of silver per ton. Mill heads averaged 15.94 ounces per ton and the tailings were reduced from 3 ounces to 1.75 by the use of the Callow flotation plant, which superseded canvas tables and cyaniding. Mining and concentrating cost 33.87c. per ounce of silver recovered, smelting and marketing 7.98c., while the output was sold for 94.14c. The average cost per ounce of silver produced during the twelve preceding years has been 16.3c. Re-treatment of the sand tailings pile was begun in May and continued until November, during which time 22,000 tons of an average value of 3.5 ounces were treated.

Report of the Patent Committee to the National Research Council

THE Commissioner of Patents in 1917, with the approval of the Secretary of the Interior, requested the National Research Council to appoint a committee to investigate the Patent Office and patent system, with a view to increasing their effectiveness, and to consider what might be done to make the Patent Office more of a national institution and more vitally useful to the industrial life of the country.

Mr. Thomas Ewing, who is a member of the Patent Committee, was the Commissioner of Patents who took that action.

The National Research Council, complying with the request, appointed a Patent Committee, consisting of: Dr. William F. Durand, chairman; Drs. L. H. Baekeland and M. I. Pupin, scientists and inventors; Drs. R. A. Millikan and S. W. Stratton, scientists; Dr. Reid Hunt, physician; and Messrs. Frederick P. Fish, Thomas Ewing and Edwin J. Prindle, patent lawyers. On the departure of Dr. Durand for Europe, Dr. Baekeland was appointed Acting Chairman of the Committee.

Four Changes Recommended

The Committee has concluded to propose a program consisting of but four features, because it believes those features are of such fundamental importance that their enactment into law would strengthen the entire system and directly and indirectly establish it upon a new and much more advantageous footing before Congress and the public; and because with a simple program, presenting comparatively little opportunity for difference of opinion as to the desirability of the changes proposed, there would be a unanimity of opinion in support of it which could not be obtained if the program were more extended.

A Single Court of Patent Appeals

The first proposal is the establishment of a single Court of Patent Appeals that will have jurisdiction of appeals in patent cases from all the United States Districts Courts throughout the country, in place of the nine independent Circuit Courts of Appeals in which appellate jurisdiction is now vested.

The existence of nine appellate courts of concurrent jurisdiction in patent cases works serious hardships. While, theoretically, the law is the same in all of these courts, there has been an irresistible tendency to drift apart in the application of the law. It has even happened in a substantial number of cases that two of the appellate courts have taken a different view of one and the same patent.

Would Benefit Industry

It would be of the utmost value to those in the United States who are engaged in industry if the present confused condition could be corrected and a single tribunal devote itself to crystallizing the fundamentals of the patent law and to educating the courts throughout the land to uniformity in applying these principles in special cases.

A bill is suggested for the establishment of such a Court, which has been advocated for many years by the American Bar Association, and is No. 5011, of the House of Representatives, 65th Congress, 1st Sess. It provides for a court of seven members, which would sit in Washington, with a Chief Justice appointed for life by the President. The appointment of the Chief Justice for life is in order that there may be an element of continuity in the Court. The other Judges are to be selected by the Chief Justice of the United States Supreme Court from the various District and Circuit Judges throughout the land, and each is to sit on the Court of Patent Appeals for a period of six years, or longer, if reappointed.

The Patent Office a Separate Institution, Independent of the Department of the Interior

The second proposal is that the Patent Office be made a separate institution, independent of the Interior or any other department. The Patent Office was originally in the State Department, but, on the formation of the Interior Department in 1849, it was made a bureau of that Department and has been so ever since.

The Committee believes that to make the Patent Office an independent bureau would greatly increase the respect of the public and Congress and the courts for it, and would make it easier to procure enlarged appropriations and better salaries than under present conditions.

A copy of a proposed bill for making the Patent Office an independent bureau is annexed to the report and its enactment is recommended by the committee.

Increase in Force and Salaries of the Patent Office

The third proposal which the committee recommends is a substantial increase in the force and salaries of the Patent Office. The patents granted by the United States Patent Office are of less average probable validity than formerly, because the number of applications for patent and the field of search are constantly increasing, while the examining force for many years has been insufficiently large and has not been increased proportionately. The inducements are so unattractive that twenty-five per cent of the examining force has resigned within the past three years. The salaries of the Patent Office examiners have been increased only ten per cent since they were fixed in 1848, when they were approximately the same as those of members of Congress. At the time the salaries of the Examiners-in-Chief were fixed, they were the same as those of Federal District Judges.

Low Salaries Paid

During the past seventy years, the compensation for technical service in almost all other directions has been increased very largely.

Congress, in creating new positions, is willing to pay technical men salaries more nearly approximating the usual compensation of such men in private service, but, having started a position at a given salary, is very loth to increase the salary. A Principal Examiner, to pass the entrance examination for the Patent Office, must himself have an education equivalent to that of a college graduate, and yet his salary is so low ($2,700 a year) that it is practically impossible for him to give

his own sons a college education. The committee believes that salaries should be paid to the examiners proportionate to those paid for equally high technical work in other departments created recently.

Recently there have been two or three decisions in which the courts have taken a more liberal attitude, holding in effect that where an invention has been used by an infringer a reasonable royalty may be awarded to the patentee based on a mere estimation or on opinion evidence, even though no exact computation can be made.

An amendment has been proposed to Section 4921, the Revised Statutes of the United States, reading as follows:

> "If proof is not offered or, in the absence of adequate proof of the amount that should be awarded as damages or profits, the court, on due proceedings had, may adjudge and decree to the owner payment of a reasonable royalty or other form of general damages."

This proposed amendment would enable the patentee in all suits where the patent has been found valid and infringed to recover at least a reasonable royalty, and would provide a money recovery in the great majority of patent suits where no recovery would otherwise be possible.

Research Vacancies in the University of Illinois

THE University of Illinois announces that at the close of the current academic year there will be eight vacancies to be filled in the research graduate assistantships maintained by the Engineering Experiment Station of the university. In addition there are available two research graduate assistantships in gas engineering, which are supported by the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

Appointments are made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of master of science will be conferred. Not more than half of the time of a research graduate assistant is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the director of the station each year not later than March 1. The nominations are made by the executive staff of the station, subject to the approval of the president of the university. Nominations are based upon the character, scholastic attainments and promise of success in the principal line of study or research to which the candidate proposes to devote himself.

Preference is given those applicants who have had some practical engineering experience following the completion of their undergraduate work. Appointments are made in the spring, and they become effective the following September.

The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of conducting investigations in the various branches of engineering and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State of Illinois. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics.

Additional information may be obtained by addressing the director, Engineering Experiment Station, University of Illinois, Urbana, Illinois.

Secretary Lane Seeks Survey of Power Resources

Secretary Lane of the Interior Department has sent to Congress requests for two appropriations for special investigations and report on the power supply. One of these is a request for an appropriation of $50,000 for a survey of the power resources all over the United States. This proposed appropriation is embodied in the Sundry Civil Bill, hearings on which are now being held before the subcommittee of the House Committee on Appropriations. If approved, the work would be done by the Geological Survey. The other request is for an appropriation of $200,000 for a report on the power supply for the industrial region of the northern Atlantic seaboard, extending in general from Boston to Washington. If approved, this work would be done by the Geological Survey and the Bureau of Mines in co-operation. The request for the $200,000 appropriation has been approved by the Secretary of the Treasury, and has been forwarded to Mr. Swagar Sherley, chairman of the House Committee on Appropriations.

Deadlock on Water Power Legislation

The water-power conferees of the Senate and House of Representatives have held another meeting lasting for three and one-half hours, and are again deadlocked upon the same question which has prevented the passage of a water-power bill for five years, namely, the question of the charge to be made.

The Washington representative of CHEMICAL & METALLURGICAL ENGINEERING reports that Senators insist that no charge shall be made for the use of water, on constitutional grounds, while the House conferees are insisting that the language of the House bill shall be used, which would give to a proposed Federal Power Commission the right to make a charge for water.

The attitude of those in Washington who are familiar with this proposed legislation is that the charge which would be made is so small in comparison with the benefits to be derived that the Senate could well recede from its position. The conferees adjourned subject to the call of the chairman, and will try to hold another meeting Monday.

Chemical Warfare—A New Weapon

Novel Views on the Future of Gas Warfare Expressed by Brigadier General Amos A. Fries—Lower Death Rate From Gas Casualties Than From All Others—The "Humanity" and Effectiveness of Gas Warfare

By Ellwood Hendrick

In August, 1917, Brigadier General Amos A. Fries, of the U. S. Engineers, was appointed to command the chemical warfare service of our Army in action. He has lately returned to the United States, and it was the privilege of the writer to spend a couple of hours in discussion with him concerning gas warfare and the chemical wing of the service. Gen. Fries has been awarded the rank of Commander of the Legion of Honor by the French Government.

The opinion seems to prevail generally that the use of poison gas, launched in breach of faith by the German High Command, has reached an end for all time; that by general agreement in convention it will no longer be endured, and that it is to be classed with the many practices of violence and debauchery of which the German army was guilty.

This is not in accord with General Fries' opinion. The Allied troops used chemical warfare in constantly increasing measure because it is an effective weapon. On the other hand atrocities were neither practiced, encouraged, nor permitted. It is General Fries' belief that the use of other chemicals besides shot and shell, having been introduced into the art of war, can never be eliminated. The situation is somewhat like that when gunpowder was introduced, and universally frowned upon as unfair and unsportsmanlike; yet it has endured.

Why Chemical Warfare Will Not Be Permanently Suppressed

The principal reasons why gas and chemical warfare is unlikely to be permanently suppressed are because

It is the most humane method of fighting, if both sides are prepared for it, while

It is the most deadly of all methods to the side that is unprepared.

The "humanity" of poison gas we shall consider shortly; the first point is that the army that is prepared against it is unlikely to be severely injured, while that which is unprepared is almost certain to meet defeat in an attack. Now, wars are usually caused by the breach of agreements, and it is seldom that a nation at war trusts its enemy. And if the enemy by the use of chemical warfare is able to win, then its opponent will have to be prepared. War has not yet reached the stage of the code duello, whereby an impartial umpire may step in and declare the fight off if unfair practices are employed. So the only safety against defeat is to be prepared against chemical attack. This takes a long time and peculiar training, while most wars are of shorter duration than that with which we have lately been engaged. The old military axiom of safety in preparedness still holds good. When the Germans launched their first clouds of chlorine the road to the Channel ports was open to them. The trouble was, as usual, that Fritz was a little slow in his thinking, and he missed his chance. The Allies obtained time enough, by a miracle of industry on the part of British and French women, to make preparations, and then, after gas warfare was started, the Allies thought faster than the Germans, and finally beat them at their own game.

Now in regard to the "humanity" of gas warfare, it should be remembered that the American troops were originally not prepared against it. Our men were saved by the British. No fewer than 700,000 British gas masks were furnished to us before the American masks arrived. Our first gas officers and troops were trained by the British, and so well trained withal that they avoided accidents. It was only by means of this help that we may be said to have been partially ready. Despite this defect in preparation the following figures are illuminating. Of our total casualties in battle about 30 per cent arose from gas, leaving 70 per cent caused by all other forms of attack such as bullets, shrapnel, machine guns, high explosive shells, etc.

Gas Caused Only 5 Per Cent of Deaths

But while the gas wounded equalled 30 per cent of our casualties, deaths from gas were only 5 per cent of the total deaths. In other words, of each 100 wounded with gas 3 to 4 die, while of each 100 wounded with bullets, high explosive, etc., 20 to 25 die. Deaths from pneumonia and other lung complications following gassing are included in the 3 to 4 per cent given. Of the total casualties from other causes, 20 to 25 per cent died, and this does not include the men who are maimed. We have more than 3000 men who have lost either a leg or an arm, not to count those who have been blinded. There is no authenticated case of permanent blindness from gas. The U. S. authorities in the very beginning prescribed the use of gas in all shells from 3 to 8 in. in diameter, and finally, last summer, the list was made to include all shells up to 9½ inches.

Against savages or semi-civilized tribes gas warfare may be made as humane as is desired. Lachrymator or tear gas will cause temporary blindness so that enemy troops may be easily captured, though within a few hours the prisoners have their sight completely restored, and are not physically injured otherwise.

The training of gas troops is of primary importance. It is required of them that they use their noses to sniff out the first sign of gases. Sensitiveness to this grows as the men remain in the service. The men must know the hazards, and yet they must not be frightened so as to make them susceptible to panic. Protection must be adequate, but not a burden. Better a little hazard than discomfort which men cannot endure.

The entire system of defense needed to be changed with the advent of mustard (dichlorethylsulphide). Theretofore with chlorine, phosgene, diphosgene (trichlormethylchlorformate, etc., the attacks were intense but short lived. Mustard, however, which boils at about 217 deg. C., remains in place, and in cold, still weather lasts more than a week after it has been spilled upon the earth. This requires a more comfortable protection and the necessity of moving troops from gassed to free areas. Very fortunately this necessary change in tactics was synchronous with the change from trench warfare to an elastic front.

Gas troops also are drilled in the use of Livens projectors and bombs, and Stokes mortars, both of which are British contributions. The Livens projectors are 8-in. drawn steel tubes, either 2 ft. 9 in. or 48 in. in length. These are loaded with loosely fitting bombs 8 in. in diameter and about 14 in. long. They are fired simultaneously in groups of 50 to 2500. The Stokes mortar is a 4-in. heavy tube, by means of which 25 to 40 bombs, fitted with fuses to break them open, may be fired per minute.

Need for Chemists as Officers

Practice also shows the need of 3 to 5 chemical warfare officers on the staff of each commanding general to augment the artillery, as well as gas troops to follow up the infantry. It is also desirable that of the Chemical Warfare Division in the field, at least 25 to 30 per cent of the officers be sound chemists.

Laboratories are absolutely essential, and these must keep in close touch with the field. Leading authorities are of the opinion that the greatest hindrance to the work of the National Research Laboratory in Washington was its inability to keep in touch adequately with the fighting line. The vast number of reports which were lost, including thousands of pages of supremely valuable data which never arrived, made the situation worse. There were sent from France during the six months 360 reports, and of these a great many have not been found to this day. Defective communications were among our most expensive troubles.

Laboratories should be recognized as an intimate part of the fighting machine, inasmuch as only by this means can the constantly changing problems of this scientific method of warfare be met. The lack of enough and of very capably manned laboratories in chemical warfare is no less than an invitation to defeat. With proper laboratory co-operation, however, chemical warfare offers the greatest range for ingenuity to both officers and men in the field and on the staff.

On the other hand it is of signal importance that chemical warfare be under military guidance, because purely laboratory methods give wrong and harmful results. An instance of this may be cited in the case of vincennite, a French preparation of hydrocyanic acid which, while remarkably toxic upon dogs, was little more than useless in the field. The British succeeded earlier than the French in achieving active co-operation between their military and chemical staffs, and they benefited accordingly, contributed more, and made fewer errors. As soon as the French obtained this co-ordination their progress was immensely accelerated. Errors of the following type are typical of laboratory work without military communication and control: too tight elastics in masks, too long rubber mouthpieces, the wrong use of such a gas as vincennite, as stated above, etc.

The first American gas troops were trained by the British for three weeks. The first independent American gas attack was made along the front of the Rainbow Division in April, 1918, and so well did the troops acquit themselves that the regiment received the decoration of the Legion of Honor, and 26 Croix de Guerre were distributed among officers and men.

Gas Troops of Incalculable Value

As the art progressed it became part of every battle plan to answer the questions, "Where can we use gas?" and "Where can we use smoke?" Then as the battle proceeded the gas troops followed the infantry, and became of almost incalculable value in breaking up machine-gun nests. The method came from the collaboration of various branches of the Chemical Warfare Service, wherein Stokes mortar bombs were employed, containing thermit and white phosphorus. They were remarkably effective. One single shot brought out 77 boches, hands up and crying "Kamerad!" This is but an incident of the ingenuity of the chemical division when it is well organized. Thermit has its faults; it cools very quickly, but the phosphorus gave it a bewildering quality. Whenever a smoke screen was needed the chemical troops were at hand to provide it. Against a massed attack a few bombs of phosgene and diphosgene were very discouraging unless the men were adequately protected, for phosgene is quick in action and gives 20 per cent fatalities. It is, however, quickly dissipated. As the war neared its end our troops were able to protect themselves against a gas attack within fifteen seconds after the first flash.

Size of American Chemical Division

Another important service developed by the gas troops was the loading of Livens bombs filled with 30 lb. of TNT, of which they fired twenty or more at a time. As these bombs did not bury themselves in the earth they completely swept the area covered by them of every living thing. More than 1000 of these were made in the field in France and put over, and 2000 more were in the making. Here also screens of smoke were often followed by screens of gas. Again, the artillery would administer the doses while the chemical officers would select the medicine. So useful were these gas troops that by the spring of 1919 there would have been no fewer than 18,000 Americans in chemical service abroad.

Not only the need of laboratories but the absolute necessity for them has been mentioned already. The Germans shot their first mustard in July, 1917, and the Allies came back with it eleven months later. Also in October, 1917, the development of the gas mask for long-time wear was begun. The final American type, which was by far the best one made, was a modification of the French Tissot mask, which permits breathing naturally through the nostrils, and in which the eyepieces are kept clear.

Another result of the research laboratory while under Colonel Bacon was the discovery that boiled linseed oil had a marked influence in retarding mustard burns.

Further research brought out the fact that this was due to metallic salts dissolved in it. It resulted in what was called "sag paste," a mixture of zinc stearate and vegetable oil, about half and half, which made an effective unguent. It did not prevent burns, but it took about six times the concentration necessary to cause burns without it.

Camouflage Gases Prepared

Camouflage gases were prepared to disconcert the enemy smellers. These were nearing completion at the time of the armistice. They made it impossible for Fritz to know what he was getting.

Other contributions in research were a saving of from one to two million dollars in specifications for camouflage paints, a fire extinguisher for aëroplanes, a new aëroplane glue, analyses of gases from German shells, the testing of masks, fabrics and smoke canisters or boxes attached to masks, because, while orders were given for each man to record the time he used his mask in gassed area, it did not work in practice. The men would not keep the records as prescribed while they were busy fighting.

Research both at home and in England resulted in technology superior to that of the Germans; indeed, toward the end of the war, the Germans' leading spy was operating in France and elsewhere to discover how mustard could be made in such quantity. The Germans at no time were able to produce over six tons of it daily. This superiority was evident as early as 1917, when rumors were rife that a German professor of humane tendencies was urging upon the International Red Cross the need of coming to a conclusion with the war, on the ground that by the spring of 1918 the Germans would launch such a fatal poison that it would produce nothing less than a holocaust among the Allies. It was suspected that this was an exponent of German fear rather than of German humanity, so word was sent back that the Allies hadn't really begun to fight with gas yet, and had no thought of quitting.

Troubles in Establishing Chemical Warfare

As for the troubles which had to be met in establishing chemical warfare their name was legion. The first requirement was personnel, and there wasn't any. "State your requirements," said headquarters, and nobody knew what they were. Personnel was, however, finally assembled, and among the splendid corps of men the following are worthy of special mention:

Colonel E. J. Atkinson (West Point '08), of the First Gas Regiment, which went over as the Thirtieth Engineers.

Colonel Richmond Mayo Smith (of Plimpton Press, Norwood, Mass., and N. Y.), in charge of supplies.

Lieutenant-Colonel Byron C. Goss, in charge of gas warfare at the front, a wonderful instructor in the subject.

Colonel G. N. Lewis (University of California), whose military sense was equal to his quick and profound chemical understanding.

Major Carl Connell (New York University), who developed the final type of mask.

Major Zanetti (Columbia University), chief liaison officer, with the French.

Major Joel H. Hildebrand (Professor at University of California), in charge of experimental field and officers' gas school.

Colonel Raymond M. Bacon (Director of Mellon Institute), in charge of research.

Major Keyes (Boston Tech.), in charge of research laboratory in Paris.

Captain Boothby, who taught mask drill.

And many others.

There was also Colonel Harrison of the British Army, who was a tower of strength in getting gas masks from England to our men, by cutting red tape and coming to the rescue. He was engaged in pharmaceutical chemistry in London, enlisted as a private at the age of 46, and died last year as a Brigadier General.

It took two months from the time munitions left the United States to reach the army at the front. While this was not always the case, it was necessary to count upon such a lapse of time. And communications, so far as forwarding reports, etc., were concerned, were no less than desperate.

Gas Inviting for Police Work, Because Effective Without Involving Fatalities

In conclusion, while conventions may agree to forbid the practice of chemical warfare, it is, as we have said, a remarkable weapon of offense. Its employment places an army at so great an advantage over an unprepared enemy that it will be difficult to trust nations to forego its use. It is exceedingly inviting for police work, because it may be made effective without involving fatal casualties or maiming. The question, therefore, must be met whether future wars shall be controlled or not. If they are to be fought under international supervision, under rules akin to an international code duello—in which event it would seem that swords alone should be the proper weapon—then we have every reason to hope for the best, so long as the supervisors do not get to fighting among themselves. On the other hand, it may be that scientific warfare will be recognized, and allowed to develop until war itself shall be prohibited by some working agreement owing to its destruction of the world's accumulated property. Half-way measures and compromises will not meet the situation. And if there is to be an international police then chemical munitions will be needed to avoid unnecessary loss of life.

War Trade Board Rulings

Export Licenses for Shipment to Switzerland—Licenses will be issued freely for the exportation of the following commodities to Switzerland, if applications are otherwise in order:

Chemical products for pharmaceutical use, including chromic acid, hydrobromic acid, salicylic acid, arsenical salts for medicinal use, sodium bromide, sodium nitroprusside, silver nitrate, amidopyrin, betanaphthol, eucaine, paraldehyde, phenacetin, aconite and preparations of alkaloids of aconite, opium and preparations of alkaloids of opium; china clay; iron and steel (except high-speed steel); essential oils; all commodities when value of shipment is less than $200.—W. T. B. R. 542 and 583.

Wolfram:—Licenses for importation of wolfram will now be issued freely.—W. T. B. R. 565.

Electrolytic Deposition of Zinc

Preparation of Cell Liquor From Fumes Collected as a Sludge in the Acid Chambers—Details of the Theoretical and Applied Electrochemistry Involved, Together With Charts and Data

By H. E. BROUGHTON

THE ore smelted by the Ducktown Sulphur, Copper & Iron Co., of Isabella, Tenn., contains slightly more zinc than copper and in the semi-pyritic method of smelting in use by this company all this zinc was lost, being carried away as fume and in the slag. The fume produced is a gray to white powder and contains upwards of 40 per cent zinc, chiefly in the form of sulphides, though the oxide and sulphate are also present.

As this fume is an impalpable powder, it is carried along with the gases entering the acid chamber and in the long, slow passage through these chambers it settles out and all the zinc compounds are converted into sulphates. The zinc sulphate, together with what other substances are carried along by the gas, and the lead sulphate formed by the corrosion of the lead chambers combine to form a heavy, white mud which collects in the pan of the chambers and which is quite insoluble in the chamber acid. The mud or sludge thus formed builds up quite rapidly and must be cleared out of the chambers frequently.

With the idea of recovering the zinc values from this mud or sludge, the company began an investigation of the possibility of using an electrolytic process. The first attempts were highly unsatisfactory. The sludge was thoroughly agitated with sufficient water to dissolve out all the zinc sulphate; the agitation was then stopped and the lead sulphate and insoluble substances allowed to settle. The clear solution was decanted and electrolyzed, using insoluble lead anodes and aluminium cathodes. The acidity of this solution ran about 13 per cent sulphuric acid and there were present all sorts of elements more electro-negative than zinc.

After it had been proved that it would be impossible to electrolyze the solution decanted from the leaching tanks without an initial purification process, a thorough investigation of the problem was begun and a process developed which would yield a practically pure zinc sulphate solution.

ELECTROLYTIC ZINC PLANT OF THE DUCKTOWN SULPHUR, COPPER & IRON CO., LTD., AT ISABELLA, TENNESSEE

An average analysis of the sludge will run as follows:

	Per Cent.
Zinc sulphate ($ZnSO_4$)	51.6
Ferric sulphate ($Fe_2(SO_4)_3$)	0.1
Sulphuric acid (H_2SO_4)	13.7
Lead sulphate ($PbSO_4$)	14.6
Copper sulphate ($CuSO_4$)	0.4
Cadmium sulphate ($CdSO_4$)	0.6
Moisture	16.0
Residue (SiO_2, S, C)	3.0
	100.0

The decant from the leaching tanks will obviously contain all these compounds except the lead sulphate and the residue. The purification process as finally perfected consisted in two main steps: First, the neutralization of the acid and the precipitation of the ferric iron; and second, the elimination of the metals more electro-negative than zinc.

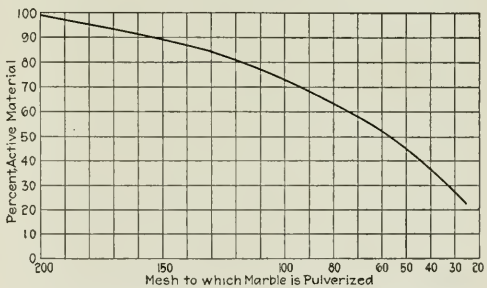

FIG. 1. CURVE SHOWING RELATION BETWEEN FINENESS OF GRINDING AND PERCENTAGE OF MATERIAL ACTIVE IN NEUTRALIZATION

Before taking up the purification process, it might be well to explain the method of handling the marble used in neutralization. From nearby marble works a waste product was procured very cheaply. This marble analyzed:

	Per Cent.
$CaCO_3$	97.28
Fe_2O_3	0.17
Al_2O_3	0.34
SiO_2	1.94
Undetermined	0.27
Total	100.00

This material was in the form of small chips about the size of rice grains and contained no dust. It made an ideal feed to the pulverizing mill and, being bone dry, could be put through very rapidly. The discharge from the mill showed by screen analysis that about 83 per cent would go through a 100 mesh and 100 per

cent through a 30 mesh. The curve in Fig. 1 shows the per cent of active material available for neutralization in this process.

Purification Process

The first step in the purification of the decanted solution was the elimination of the sulphuric acid and the ferric sulphate. This was accomplished in two steps: First, the neutralizing of the acid and the consequent precipitation of the $Fe(OH)_3$ from the neutral solution and second, the filtering of the pulp resulting from the first step.

Pulverized marble was used to neutralize the sulphuric acid and was added to the solution in a large mechanically-stirred tank. Steam coils heated the solution to about 60 deg. C., and the action taking place may be expressed as

$$CaCO_3 + H_2SO_4 = CaSO_4 + H_2O + CO_2. \quad (1)$$

The reaction is complete and the operation simple. As the $CaCO_3$ will cease to act as soon as the solution is neutral, there is no danger of carrying the reaction too far and making the solution alkaline. This was a decided advantage, as the zinc would be precipitated even from a slightly alkaline solution.

Loss in Zinc Small

The $CaSO_4$ thus formed was fairly insoluble and was easily eliminated on a filter. By a careful washing of the filter cake, the loss in zinc was very small. We have found the Oliver continuous filter to be a most excellent filter for this work, the loss of zinc in the filter cake being less than 5 per cent, while the wash water necessary to accomplish this result was too small to lower materially the concentration of zinc in the filtrate. The only drawback to this process was the frequent cleaning necessitated by the slight precipitation of $CaSO_4$ in the pores of the filter cloth as the filtrate cools in passing through. Hot water and stiff brushes, however, applied daily kept the pores nicely open. An occasional bath with hot dilute muriatic acid was found beneficial.

The electro-potential of metallic zinc against a normal solution of its cathion (32.5 grams of zinc per liter) is +0.49 volts, and any metallic element which has a lower potential than this under the same conditions of concentration should be replaced in solution by a zinc ion or ions, when the solution containing such metals is brought into contact with metallic zinc. A slightly acid solution accelerates the reaction.

Thus, copper in a copper sulphate solution will be completely eliminated from solution as a spongy deposit on a piece of zinc according to the reaction expressed as

$$2Cu^{++} + Zn_2 \rightarrow Cu_2 + 2Zn^{++} \quad (2)$$

Since any metal capable of forming an insoluble sulphate is automatically eliminated from the solution and left as a residue in the leaching tanks, all the first group and 2B group metals are thus taken care of. This leaves copper, cadmium and bismuth, and the slight amount of iron brought in with the acid used to accelerate the action, to be precipitated on zinc.

The following table gives the electro-potentials of these elements against a normal solution of their cathions and the difference in potential between each element and zinc under the same conditions:

Element	Potential in Volts	Potential of Zinc	Difference in Potential, Volts
Copper	−0.61	+0.49	1.10
Cadmium	+0.14	+0.49	0.35
Bismuth	−0.67	+0.49	1.16
Iron	+0.06	+0.49	0.43

These potentials are true only for the pure metal against a pure normal solution of its cathion. However, it provides a basis for reasoning, and in actual practice it is found that the reaction does occur quantitatively and quite rapidly.

In the practical application of the principle, the zinc mass must be of large surface and the contact with the solution positive and of as long duration as is practical. The concentration of zinc ions is naturally enormously larger than the concentration of the other metals, and for this reason the actual voltage relations expressed above for ideal conditions probably do not obtain, but sufficient potential difference does exist to procure the desired results.

Time Element Important

It has been found experimentally that, under the conditions imposed by the problem, a concentration of about 0.2 per cent acid gives the best results with the least harm: that is, an average of 0.2 per cent H_2SO_4 in the whole process. Now in the practical method of handling this process, the time element is quite important and the amount of acid added to the neutral filtrate from the first step should be proportioned to give an average of 0.2 per cent H_2SO_4 throughout the time of contact with the zinc mass. This procedure should be regulated to give a maximum of 0.1 per cent H_2SO_4 in the resulting purified solution, or as much less as is practical.

In practice, the above reactions were carried out in two tanks three feet in diameter by seven feet high, operated on the Pachucca principle; the mass of zinc, in the form of broken sheets, nodules and odds and ends from the stripping room, was supported about nine inches above the bottom of the tank on a grating and extended up to within a foot of the top of the tank. A lead pipe extended down through this mass to below the grating. A small air pipe was led down and turned up inside the lead pipe and the air admitted here caused a rapid and thorough circulation of all solution in the tank over the zinc mass. It was feared at first that this method would not work after the zinc mass had become coated with the mossy deposit of the metals it replaced in solution. These fears were groundless, however, as two tanks working in series handled continuously and efficiently the work imposed upon them.

The copper in solution was completely removed in a very short time and the slight amount of bismuth present was also easily eliminated, but the cadmium was a trying proposition, and so far it has been found impossible in these tanks to eliminate it absolutely, no matter how long a time of contact is maintained or what concentration of acid is used.

The precipitated cadmium will redissolve appreciably if allowed to stand in an even faintly acid solution and, since this element is the greatest enemy to a pure zinc product, it was found best to filter all the solution as fast as it left the precipitating tanks, rather than allow the small amounts of solids to settle and then decant a major portion of the solution, as would seem the natural

procedure. The solution from these tanks, after being filtered, was ready for electrolysis.

Electrodeposition of Zinc

There is a constant peculiar to each element known as the electro-chemical-equivalent. The derivation of and laws pertaining to these constants are perfectly familiar to the chemical and metallurgical world, and too much profound thought has been given to the subject for this article to add anything further. Suffice it to say that for the element zinc the electro-chemical-equivalent is 1.2211 grams of zinc per ampere hour. Then, theoretically, for every ampere hour of work applied to a suitable solution containing any zinc salt in any concentration, we should recover 1.2211 grams of metallic zinc on the cathode. This constant expressed in pounds of zinc per 1,000 ampere hours is 2.69.

Suppose in the cell we use an average current of 10,000 amperes per day of twenty-four hours, we should expect to recover

$$\frac{10{,}000 \times 24 \times 2.69}{1000} = 646 \text{ pounds of zinc per day.}$$

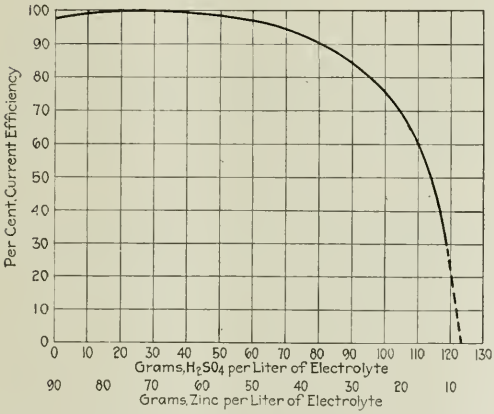

FIG. 2. CURVE REPRESENTING AVERAGE OF A LARGE NUMBER OF POINTS ALL MEASURED UNDER THE SAME CONDITIONS OF TEMPERATURE, CURRENT DENSITY AND ELECTRODES, IN A SOLUTION CONTAINING ONLY $ZnSO_4$ AND H_2SO_4

If the electrolytic plant operated at 100 per cent current efficiency, this obviously would be the yield. Unfortunately, it is impossible in practice to reach 100 per cent efficiency and a term, "current efficiency," has come into use to express the ratio of zinc produced to the theoretical yield. The curve shown in Fig. 2 indicates the current efficiency of a certain zinc sulphate solution when electrolyzed. This curve will be discussed later.

A solution of any zinc salt forms an electrolyte. The electrical resistance of all electrolytes varies with the salt concentration and with different salts. Thus the electrical resistance of a zinc sulphate solution of, say, 1 N concentration differs from the resistance of a 1 N solution of zinc chloride; and, further, a 1 N solution of sodium sulphate is still different in electrical resistance. Finally, the electrical resistance of a 1 N zinc sulphate solution is quite different from the resistance of a 5 N, or a 1/100 N solution. The laws governing this variation in electrical resistance have been very carefully studied by Ostwald, Kohlrausch and A. A. Noyes.

The researches have shown the existence of certain relations between the concentration of a salt in solution and the electrical resistance of that solution; and further, they have classified the various salts into groups in which the effect on electrical resistance of the solution containing any one member of the group in solution is the same. As a matter of fact, the change in resistance of the electrolyte with the change of salt or concentration is an effect and not a cause.

The cause lies, first, in the fact that it is the individual ion that carries the current through the electrolyte and therefore an increase in concentration will cause an increase in the amount of current carried at a given e.m.f., or a decrease in resistance; and, second, in the speed at which the ion travels through the solution or, as it is called, the speed of migration of the ion. Thus a fast traveling ion will show in solution a greater amount of current transported through the electrolyte (that is, a decrease in resistance) than a slower moving ion if both are present in equivalent concentration.

Since, therefore, the number of ions available and the speed at which each travels determine the electrical resistance of the electrolyte, it is evident that a concentrated solution will be of the lowest resistance provided the per cent ionization of the salt in solution is high. Thus a third factor enters, namely, the per cent ionization of the salt. For a salt may be very soluble, so that its concentration in solution is high, and yet the concentration of ions, or current carriers, may be very low, due to the small per cent of the salt ionized.

When a zinc sulphate solution is electrolyzed the chemical reaction taking place may be expressed somewhat as follows:

$$ZnSO_4 + 2\oplus + 2H_2O = 2H_2SO_4 + O_2(\text{gas}) + Zn_2 \quad (3)$$

While this equation is not strictly true, it serves to express the reaction in a simplified form, indicating the electrical charges of 193,000 coulombs of electricity. If 100 per cent recovery were possible, oxygen gas and metallic zinc would be the only two products of electrolysis. As the acid formed by electrolysis increases, the number of hydrogen ions from the dissociated acid increases, and as the hydrogen ion in solution acts as a metal and therefore travels toward the cathode, some of the hydrogen ions are certain to strike the cathode, give up their electrical charge and be deposited out as hydrogen gas. The amount of hydrogen gas thus formed represents a direct loss, and the current efficiency based on zinc recovery is therefore decreased in direct proportion to the amount of hydrogen involved.

It has been determined that the velocity with which the hydrogen ion migrates toward the cathode, in an electrolyte under an electrolytic pressure of 1 volt, is 0.0032 centimeter per second, while under the same conditions the velocity of the zinc ion is 0.00048 centimeter per second, or the velocity of the hydrogen ion is 6.66 times the velocity of the zinc ion. This difference in speed would mean that one hydrogen ion could travel 6.66 times as far as one zinc ion in a given time, or equally as far as 6.66 zinc ions.

Zinc is a bivalent metal, while hydrogen is univalent;

then from the reaction equation (3), two hydrogen ions are formed every time one zinc ion is plated out of solution (assuming 100 per cent ionization of the acid formed).

Since it is the ionic movement which forms the so-called flow of electrical energy through the solution, it is evident that the greater the number of hyrogen ions in solution the faster will the electrical energy flow through the solution; or, in other words, the lower will be the resistance of the solution.

It is obvious that in the electrolysis of a zinc sulphate solution the SO_4 ion is unaffected and its concentration therefore will remain constant. Now as the concentration of the hydrogen ion increases, due to the formation of metallic zinc on the cathode by the reaction equation (3), a steadily increasing amount of un-

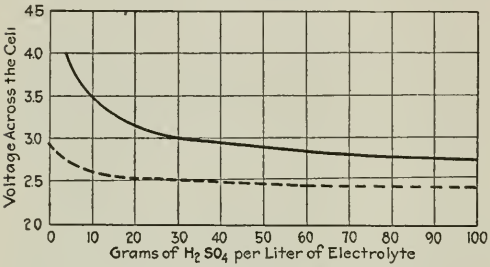

FIG. 3. VARIATION IN VOLTAGE WITH CHANGE IN ACIDITY

dissociated H_2SO_4 will be formed and therefore all the hydrogen ions released are not available as energy carriers. The concentration of $ZnSO_4$ will directly affect this result, for by the law of mass action $\frac{(H_2) \times (SO_4)}{(H_2SO_4)}$ = a constant and due to the high concentration of $ZnSO_4$ there will be present a large excess of SO_4 ions over those required by the hydrogen ions. Or in other words, in order to fulfill the conditions expressed by the law of mass action, a much greater percentage of the hydrogen will be present as undissociated H_2SO_4 than if there were no $ZnSO_4$ present in the solution.

So the net result in the conductivity of the electrolyte is considerably less than might be anticipated from our study of the relationship between the migration velocities of the hydrogen and zinc ions.

If the zinc sulphate and the sulphuric acid in the electrolyte were completely ionized, however, then the conductivity of the electrolyte would increase rapidly with increase in acidity and more and more hydrogen gas would be plated out as the concentration of the hydrogen ion increased. To carry this result further, when the concentration of hydrogen ion equals 1/6.66, that of the zinc ion, then the number of hydrogen ions coming in contact with the cathode per second would be equal to the number of zinc ions reaching the cathode; and since the current efficiency is the ratio of zinc recovered to zinc theoretically deposited by a given current, this efficiency will be only 50 per cent at this point. Since, however, a varying proportion of the hydrogen ions are suppressed by the high concentration of the SO_4 ions, this relation is not strictly true in practice.

Based on actual measurements under as nearly perfect working conditions as it was possible to obtain, the curve in Fig. 2 represents the relation between acidity of the electrolyte and the current efficiency. It should be noted that the current density at which the points on this curve were measured is 17 amperes per square foot, and the actual current density used in operating the plant varied between this figure and 20 amperes per square foot. The current density is the total current per cathode divided by the area of the cathode exposed to the electrolytic action. This so-called current density is chiefly important as a means of classifying the various effects that the other variables, as, for instance, acidity, impurities, etc., have on the efficiency of recovery; for, as a general rule, the lower the current density under any conditions the higher will be the efficiency. The best working conditions seem to be about 20 amperes per square foot, or a trifle under.

Since for every gram equivalent of zinc plated out, 98/2, or 49, grams of H_2SO_4 are formed, it is evident that very nearly one and one-half grams of acid are formed per gram of zinc plated out. Thus, the derivation of the upper scale of abscissa measurement becomes evident.

This curve represents ideal conditions, both chemically and electrically, and in practice it was never possible to obtain better than 70 per cent current efficiency over any given period of time. However, the curve shows what is possible and undoubtedly could be approached more closely by a more careful refinement of the process.

Voltage Requirements

The electromotive force required to electrolyze a zinc sulphate solution is made up of two factors—first, the dissociation voltage of the salt, and second, the resistance of the path through the electrolyte. The dissociation voltage for zinc sulphate is about 2.35 volts at 15 deg. C. for the concentrated solution used. This value is calculated from the heat of formation in calories per mole of cathion and varies with the temperature of the solution. The errors entering into the calculation due to inexact measurements render the final result rather uncertain, but from a good many measurements the value of 2.35 volts seems to be fairly accurate.

From the above discussion on the variation in conductivity of electrolyte due to change of acidity, it will be seen that since the voltage drop through the solution is equal to the current flowing in amperes multiplied by the resistance of the path in ohms, the potential difference across the electrodes will vary with the acidity of the solution. Therefore the voltage across the electrodes is equal to (2.35 + a variable) volts. And since this variable reaches its maximum value when the acidity is zero, the voltage across the electrodes should decrease as the electrolysis continues, and this is found to be the case. The accompanying curves in Fig. 3 show the variation in voltage with change in acidity for a certain set of conditions. And while the variation of these conditions would change the numerical value of the ordinates against which this curve is plotted, the general characteristics of the curve would be the same.

The variation in dissociation voltage mentioned above due to temperature change is usually expressed as a function of the absolute temperature by the ratio $\frac{\Delta E}{\Delta T}$

where ΔE is the change in electromotive force due to a change in the absolute temperature, ΔT. The value of this fraction for the range of temperatures permissible in electrolyzing a zinc sulphate solution is

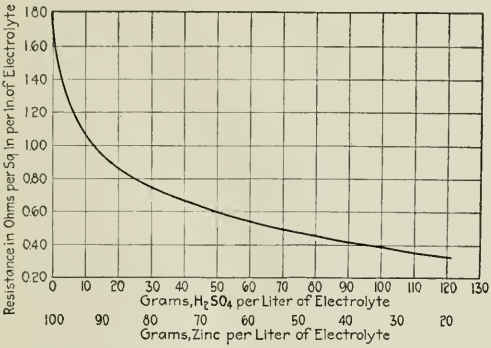

FIG. 4. ELECTRICAL RESISTANCE OF ELECTROLYTE MEASURED BETWEEN C.P. ZINC ELECTRODES

slight, and for all practical purposes the value of 2.35 volts is correct for a pure zinc sulphate solution of 2 N or stronger.

Assuming, then, our dissociation voltage as constant at 2.35 volts, and further assuming that the current flowing through the solution is constant, then the only variable left which can affect the potential difference across the electrodes is the change in the electrical resistance of the electrolyte. Since this change in electrical resistance is directly due to the increase in acidity caused by the electrolytic action as explained above, it is evident that a knowledge of this change of resistance is of considerable importance. The accompanying curve (Fig. 4) shows the decrease in electrical resistance due to a corresponding increase in acidity, as a zinc sulphate solution containing at the start 100 grams of zinc and 0.0 grams of acid per liter of solution was electrolyzed.

By Ohm's law, the potential difference between two points in an electrical circuit is equal to the electrical resistance between these two points multiplied by the current flowing in the circuit. Therefore assuming a constant current of "A" amperes and resistances of "r" ohms from anode to cathode, the potential difference between the anode and the cathode would be (2.35 + Ar) volts. The dotted curve in Fig. 3 shows the variation of this voltage with increasing acidity. By comparing the theoretical dotted curve with the full line curve based on actual measurements, the similarity in the two is at once evident, although the numerical values for the ordinates are different. This difference in ordinates is due to two facts—first, the solid curve was obtained under actual working conditions while the dotted curve was plotted from data obtained under ideal conditions, and second, the current density in the two was quite different.

Energy Consumed

In buying electrical energy, we pay for the watt-hours consumed, and a watt-hour is the product of the current flowing in amperes times the electromotive force in volts times the time in hours. It is evident, then, that the cost of electrolyzing a zinc sulphate solution is going to vary only with the variation in voltage, since the current and time are constant qualities; and furthermore that this cost will vary with the acidity of the solution, since this is the factor which causes a variation in voltage. Therefore the higher the acidity of the solution to be electrolyzed the cheaper will be the power costs. Unfortunately, however, the higher the acidity the lower is the current efficiency or the actual amount of zinc recovered. We have, then, a case of two conflicting factors; for with zero acidity we should get 100 per cent current efficiency, but our voltage would be high, while with high acidity our voltage would be low but the yield of zinc would be poor. Obviously there is a zone of best working conditions which it would be well to determine. Assuming a constant current flowing through the solution and our theoretical voltage variation as expressed above, and using the values for the variation in resistance as shown by actual measurements in Fig. 4, we can calculate the power in watts or the energy in watt-hours required to produce a pound of zinc under varying conditions in acidity. Furthermore, from the acid-efficiency curve, Fig. 2, we can pick off the values in percentage yield of zinc under similar conditions of acidity, and by combining these figures we can obtain an expression of the kilowatt-hours required to produce a pound of zinc under varying conditions of acidity in electrolyte. The dotted curve in Fig. 5 represents such a calculation, while the solid curve represents the power required to produce a pound of zinc under actual operating conditions with variation of acidity in the electrolyte. The striking similarity between these two curves is a further proof of the theories advanced.

Electrolytic Practice

While all of the foregoing theories must be kept in mind, in practical electrolytic zinc work there are a

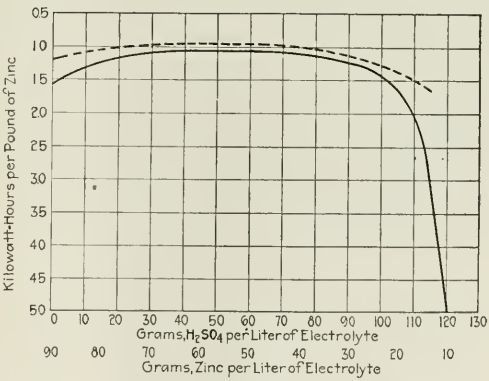

FIG. 5. DOTTED CURVE REPRESENTS THE AVERAGE OF A NUMBER OF POINTS CALCULATED FROM THE DATA OBTAINED AS EXPLAINED IN THE TEXT. SOLID CURVE REPRESENTS ACTUAL MEASUREMENTS AND WITH ALLOWANCE FOR ERRORS IN MEASUREMENT IS ENTIRELY COMPARABLE WITH THE DOTTED CURVE

great many other factors which still further complicate matters. One of the most important of these factors is the effect of impurities in the electrolyte on the deposit and also on the efficiency of recovery. In the first

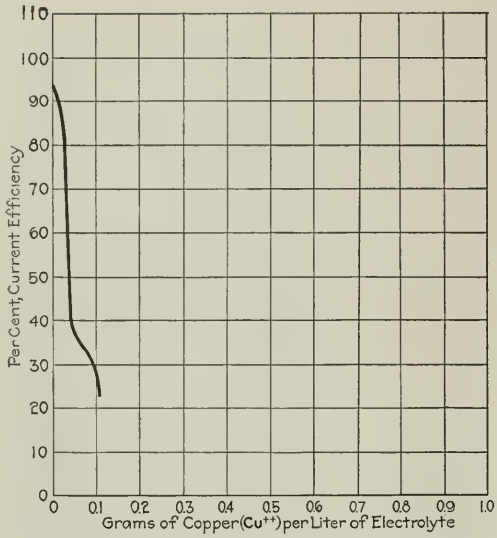

FIG. 6. CURVE SHOWING THE EFFECT OF VARYING AMOUNTS OF COPPER ON THE EFFICIENCY OF RECOVERY

part of this paper dealing with the purification of the electrolyte, the fact was brought out that metals with a lower electro-potential than zinc could be replaced from their solutions by metallic zinc. If this purification process is not carried out to completion, traces of other metals will be found in the electrolyte and, under

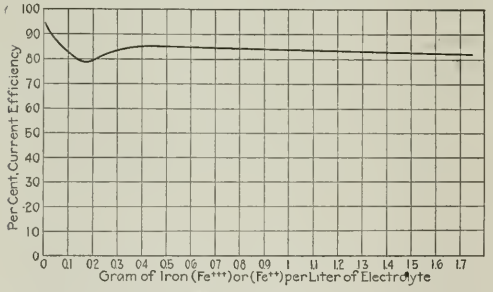

FIG. 7. CURVE SHOWING THE EFFECT OF VARYING AMOUNTS OF IRON IN THE ELECTROLYTE ON THE EFFICIENCY OF RECOVERY

certain conditions, will replace the zinc plated out of solution with astonishing rapidity, eating holes in the deposit and sometimes completely removing a heavy deposit of zinc. The chief offender in this line appears to be copper, as little as 40 milligrams of copper (Cu^{++}) per liter of solution being absolutely fatal to electrolysis. The curves shown in Figs. 6 to 9, inclusive, show the effect on the percentage current efficiency (ratio of actual zinc recovered to theoretical recovery) of varying amounts of the more common contaminating metals. These curves are the results of actual measurements in a solution containing 80 grams of zinc per liter, 2 to 3 per cent acid and varying amounts of the impurities under discussion. The current density in all cases was maintained at 17 amperes per square foot.

The point might be raised that these curves represent only one set of conditions in regard to zinc and acid concentration in the electrolyte. This is quite true; but in the first place, this set of conditions was found to be the best all-round working conditions for the plant and is, therefore, the only set in which we are interested. In the second place, experiments showed these curves to be representative of a family of curves when the zinc and acid concentration were varied. All the curves in each such family were quite similar in contour and varied only by a constant. As would naturally be expected, the efficiencies were always lower when the acidity was increased and the effect of any one impurity was therefore accentuated in a more strongly acid solution.

These curves are true only when the one impurity under discussion is the only impurity present in the electrolyte, and the cumulative effect of a number of

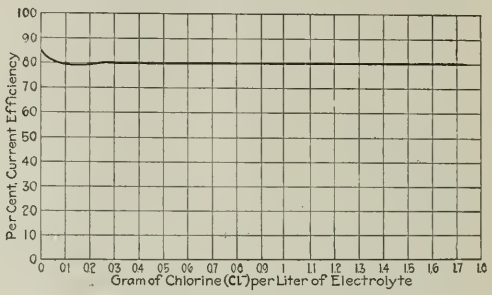

FIG. 8. CURVE SHOWING THE EFFECT OF VARYING AMOUNTS OF CADMIUM ON THE EFFICIENCY OF RECOVERY

these impurities in one solution undergoing electrolysis is naturally greater than any individual case such as we have discussed. This cumulative effect, however, is small through the range of concentration actually met with and the best way in which to determine it is by an actual measurement of the efficiency under the conditions it is desired to investigate.

The curve in Fig. 9 showing the effect of chlorides represents a series of measurements made on a solution containing varying amounts of sodium chloride and is interesting chiefly because it shows that the presence of an anion other than the SO_4 radical does not ma-

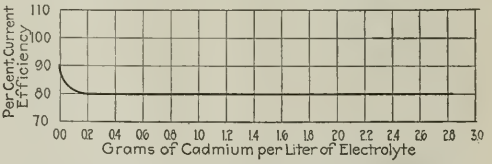

FIG. 9. CURVE SHOWING THE EFFECT OF VARYING AMOUNTS OF NaCl IN THE ELECTROLYTE ON EFFICIENCY OF RECOVERY

terially affect the yield of zinc. The chlorides do, however, attack the insoluble lead anodes to an appreciable extent.

There are some impurities which apparently can build up in the electrolyte to a comparatively high concentration without any bad effects. These impurities are practically all above zinc in the electromotive series

and include such metals as chromium, manganese, aluminium, magnesium and the alkalies.

A great deal has been said and written concerning the presence of an alkali sulphate in the electrolyte, some authors claiming a marked improvement in efficiencies with sodium sulphate present, others claiming that even small amounts are detrimental. In the Nahnsen process for electrolytic refinement of impure zinc anodes, from 100 to 300 grams of sodium sulphate per liter are used. In the author's invesigation of the effect of sodium sulphate in the electrolyte on the efficiency, varying amounts were used, but no variation in current efficiency resulted except when a high percentage of acid was present. It is probable, therefore, that the presence of sodium sulphate in the electrolyte merely contributes an increase of SO_4 ions, thereby causing a corresponding suppression of hydrogen ions and an increase in current efficiency, or yield.

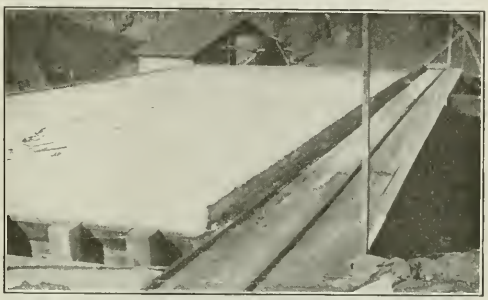
At various times in the history of electrolytic work, not only in zinc but in the electrolytic recovery of all metals, some one operator has discovered and used some simple organic compound in his process which has had decidedly beneficial results. These substances are usually called "additive agents" and probably the most common is ordinary ground glue. The author tried several of these compounds and, while the results were not at all certain, yet there seemed to be less gassing, less heating and a more uniform current distribution when a small amount of glue was kept in the electrolyte circulating system. Excessive amounts were decidedly bad, causing an increase of gassing and a pitting of the surface of the deposited zinc.

At Ducktown the electrolysis was carried out in lead-lined wooden tanks, the lining of each tank being entirely separate from all the others. It was feared at

FILLING THE STORAGE TANK WITH SLUDGE FROM THE ACID PLANT CHAMBERS. THE DUMP CAR AND TANK ARE LEAD LINED

first that this construction might cause trouble due to short circuits and ground leaks, but in practice the lead-lined tanks proved very satisfactory. The partition between each two tanks was broad enough to support the equalizing bus bar and the insulators on which one end of the electrodes rested. There were in all thirty tanks or cells in series with ten cathodes and eleven anodes per cell. The voltage across the entire thirty cells was 115 volts, or 3.83 volts per cell. The loss in contact between the electrodes and bus bars was about 0.4 volts per cell, giving an actual useful voltage of 3.43 volts. The line drop and leakage on the total electrical circuit was about 6 volts. Expressing these figures in percentages, the actual useful voltage was 85 per cent, the contact loss 10 per cent and the line drop loss 5 per cent.

While the cells were connected in series electrically, they were fed individually with solution from a common launder, or we might say the circulating system was a parallel circuit. This circulating system was so arranged as to maintain a constant concentration of zinc and acid in the cells. The way in which this was



STORAGE TANK FULL OF SULPHATE SLUDGE

accomplished was quite simple. A large air lift was installed which was fed from a collecting tank under the floor of the cell room. Across the front of the cells there was built a lead-lined launder; overflow pipes from each cell discharged their solution into this launder; the launders in turn discharged into the collecting tank above referred to. The solution was then pumped by means of the air lift to a distributing tank mounted well above the level of the cells. It was led by means of a lead pipe into a lead-lined distributing launder which in turn fed each individual cell through a small lead pipe. The rate of circulation was about 100 gallons per cell per hour.

From the lower circulating tank a second and much smaller air lift continually withdrew a small amount of solution. The solution thus withdrawn was returned to the leaching tanks, while at the same time an equal amount of strong neutral solution was added to the circulating system by means of the top circulating tank. The quantity of solution added and withdrawn was so controlled as to maintain a constant concentration of zinc and acid in the cells.

The average analysis of the solution in the cells showed 70 grams of zinc per liter and about 3 per cent acid, and under these conditions of electrolyte the current efficiency averaged 60 per cent.

The only unfortunate feature in this process was the rehandling of so much solution; for in order to neutralize the acid by the calcium carbonate method, the solution had to pass through the Oliver filter a number of times, and in each of these passages some zinc was lost, so that the total loss in zinc in the filtration was high, notwithstanding the fact that each individual passage through the filter showed excellent recovery.

The electrodes used were the usual aluminium cathodes and lead anodes. These electrodes were suspended from aluminium bars, to which they were rigidly

bolted. These bars in turn rested on the aluminium equalizing bus on one end and on a porcelain insulator on the other end. At first the pressure between the aluminium bar and the bus was depended on for electrical contact, but this caused no end of trouble. If one contact became slightly corroded between the surfaces while another contact on the same bus remained good, then the electrode with poor contact would cease to carry any current due to the increased contact resistance, while the electrode with good contact would double its current. Under these conditions the electrode with poor contact would cease to be effective and the zinc deposited on it if a cathode, or by it if an anode, would immediately begin to dissolve in the acid electrolyte, while the electrode carrying double its normal current would become dangerously hot and give off considerable gas. In order to get away from this trouble and insure certain contacts, the aluminium bars from which the electrodes hung were eventually securely bolted to the equalizing bus. A further prevention was the coating of the surfaces of the contacts with vaseline to insure

ONE SIDE OF THE CELL ROOM, SHOWING THE FEED AND OVERFLOW SYSTEMS AND THE METHOD OF HANGING THE ELECTRODES. THERE ARE SHOWN ONLY 3 ANODES AND 2 CATHODES PER CELL

against corrosion. In this way very satisfactory operations were obtained.

Above the surface of the solution during electrolysis there is a great deal of gas and mist, the mist apparently being very fine drops of the electrolyte carried into the air by the gas bubbles rising from the electrodes and bursting at the surface. This mist was very irritating to the mucus membranes of the men working on the cells, and in order to eliminate it the tops of the cells were closed in by a sort of hood which could be raised at will out of the way of the operator. A ventilating fan, connected up with these hoods by means of a system of flues, drew all this mist out of the building and discharged it harmlessly out of doors.

The thirty cells in series were divided into three groups of ten, and a fourth group of ten cells was held as a reserve. The current was led to and from each of these sections through large single-pole switches. These switches were so arranged that any three of the four groups of cells could be connected in series at one time. Furthermore, the fourth group could be cut in and any other group cut out without shutting down the generator. By this means an absolutely continuous operation was maintained, the groups of cells rotating in order and each group being plated 72 hours. By this method one group of ten cells was cut out each day of twenty-four hours and another group cut in, thus giving a full day to the stripping and cleaning of the cathodes from each group of cells.

The deposit of zinc on the cathodes was usually fairly smooth, a few nodules appearing on the surface and occasionally some treeing, but on the whole a smooth deposit of uniform thickness was obtained. A great deal of trouble was encountered at first with a blistering or bulging of the deposit of zinc. The metal did not appear to cling tightly to the aluminium cathode. This trouble was never completely cured but was relieved very materially by a careful and painstaking cleaning of the aluminium cathodes each time they were stripped.

The zinc recovered was on the whole of very superior quality, the chief impurity being cadmium. The average of a great number of analyses gave 99.90 per cent zinc, with about 0.05 per cent cadmium, 0.03 per cent lead and the rest iron and copper.

The power required to produce a pound of zinc varied from 2.5 to 2.8 kw.-hr.

The sheet of zinc stripped from each side of the cathode will weigh about ten pounds. The stripping of these sheets is a very simple operation; one man can strip both sides of as many as 240 cathodes in ten hours.

In order to market this zinc it must be put in the form of 50-lb. slabs. This means melting all the electrolytic zinc stripped, but as the melting process is a very simple one and almost any type of furnace can be adapted to this purpose, this problem was never a serious one. The zinc in melting down has a tendency to form a spongy mass. Furthermore, while the melting point is about 420 deg. C., the metal must actually be melted at a temperature around 700 deg. C., in order that it may be poured successfully. And at this temperature care must be exercised or the loss by oxidation will be high. It has been found that the addition of a small amount of ammonium chloride to the molten bath has a tendency to break up the sponge zinc and also to minimize the loss by oxidation. The total loss in melting should never exceed 4 per cent of the metal melted, while with large pots or a reverberatory hearth this loss should be materially decreased.

The Aluminium Bronze Industry

By W. M. Corse

METALLIC aluminium has been known for a long time, and its use in copper alloys was discovered about 1855 by Lord Percy. The high cost of production of metallic aluminium retarded its commercial development, and it was not until the discovery of the electrochemical processes for its production that it came to be known as a common metal.

I have been particularly interested, for the past few years, in working with the alloy known as aluminium bronze, which is usually composed of approximately 90 parts of copper and 10 parts of aluminium, by weight. This alloy has many properties similar to the copper-tin bronzes, and it has been of interest to find just where the copper-aluminium bronzes could be sub-

*Read before the Institute of Metals, A. I. M. E., at Milwaukee, Oct. 9, 1918.

stituted for the copper-tin bronzes, and in that way conserve the use of metallic tin.

Copper-aluminium bronzes have practically double the tensile strength of tin bronzes, so that a smaller cross-section frequently can be adapted, with the same mechanical result. Their resistance to shock is superior to that of the copper-tin bronzes, and their resistance to wear is in some cases superior and in some cases practically equal. Consequently, for many mechanical uses, where a hard bronze is desired to replace one containing 10 to 11 per cent of tin, for example, an aluminium bronze of about the composition mentioned will be found worth investigation. Undoubtedly no two alloys possess exactly the same properties, and when a substitution of one for the other is desirable it is necessary to work out special methods of handling the substitute in order to get practically the same results.

As is frequently the case in such work, special properties are found to be superior to those of the metal originally used and other properties are discovered to be not so good. As a particular instance of the substitution of aluminium bronze for phosphor bronze, I would cite its use in worm gearing. The following table and curves taken from my paper[1] on this subject before the Society of Automotive Engineers will give an idea of the different properties:

TABLE I

PHYSICAL PROPERTIES OF PHOSPHOR BRONZE

Composed of 88.7 parts of copper, 11 parts of tin and 0.3 parts of phosphorus

Ultimate tensile strength, lb. per sq.in.	35,000-40,000
Yield point, lb. per sq.in.	22,000-25,000
Elongation in 2 in., per cent	6-10
Reduction of area, per cent	7-9
Specific gravity at 20 deg.	8.8
Brinell hardness number (500 kg. load for 30 sec.)	75-85
Pattern maker's allowance for shrinkage, in. per ft.	0.125
Weight per cu.in., lb.	0.31
Compression, elastic limit, lb. per sq.in.	16,000
Coefficient of friction	0.0040
Modulus of elasticity	12,000,000 to 14,000,000
Resistance to impact, Fremont notched-bar test (fractured section 7 x 10 mm.), kg.meters	2 to 4
Endurance of alternation impact, Landgraf-Turner or Arnold test, alternations	150 to 400
Resistance to shear by impact, McAdam machine, ft.-lb.	300 to 450

Aluminium bronze containing 10 per cent of aluminium and 1 per cent of iron has the physical properties shown in Table II.

TABLE II

PHYSICAL PROPERTIES OF ALUMINIUM BRONZE

Containing 10 per cent of aluminium and 1 per cent of iron

Ultimate tensile strength, lb. per sq.in.	65,000-80,000
Yield point, lb. per sq.in.	23,000-28,000
Elongation in 2 in., per cent	20-30
Reduction of area, per cent	21-29
Specific gravity at 20 deg.	7.5
Brinell hardness number (500 kg. load for 30 sec.)	92-100
Pattern maker's allowance for shrinkage, in. per ft.	0.22
Weight per cu.in.	0.27
Compression, elastic limit, lb. per sq.in.	19,000
Coefficient of friction	0.0025
Modulus of elasticity	15,000,000-18,000,000
Resistance to impact, Fremont notched-bar test (fractured section 7 x 10 mm.), kg.-meters	7 to 10
Endurance of alternating impact, Landgraf-Turner or Arnold test, alternations	3500 to 5500
Resistance to shear by impact, McAdam machine, ft.-lb.	750 to 850

It is of interest to note that aluminium bronze would undoubtedly have been substituted for phosphor bronze before this had the manufacturing difficulties with the former been surmounted. Aluminium bronze, when cast in the foundry, presents about as difficult a problem as I have ever seen. It is very sensitive to gas absorption and must be handled extremely carefully to insure good castings. It is similar, from a foundryman's standpoint, to manganese bronze, in that it requires large risers and careful pouring to insure clean castings. Several years' work on this alloy has demonstrated conclusively that it is perfectly possible to make as large a percentage of good castings from it as from any other non-ferrous alloy. It seems to me therefore that its use should be increased, particularly in view of the shortage of tin at the present time, and undoubtedly new fields will be opened up as its various properties are better known.

One feature that stands out prominently, which was mentioned by the eminent English investigators of this type of alloys and published by them in the 8th and 9th reports of the Alloys Research Committee of the Institution of Mechanical Engineers of Great Britain, is the fact that cast aluminium bronze possesses properties equal to those of rolled aluminium bronze. Nearly all copper-base alloys are improved by rolling processes, but the copper-aluminium alloys seem to possess equally good properties when cast or rolled; this is a remarkable metallurgical fact. Another important property of these copper-aluminium alloys is their resistance to alternating stress. Many tests indicate that their resistance is greater in this respect than that of some steels, and I have seen instances when cast aluminium-bronze bolts have outlived five steel bolts in foundation work subject to severe shocks. I mention these various instances to indicate that work originally started as research for substitution of one material for another frequently develops an article which has properties not possessed by the original metal or alloy.

I have dwelt particularly on the aluminium bronzes because recently I have done more special work on them than on other alloys, but I believe that the use of aluminium itself in many combinations of metals is a very important subject for investigation. Undoubtedly after the war the cost of aluminium will be reduced from its present price, and considering its low specific gravity it offers a very interesting and important field for research in the non-ferrous business. Naturally, if combinations containing aluminium can be developed, in view of a probable increasing supply of metal the cost will be reduced. This will benefit the industry generally and will immediately conserve tin.

Niagara Falls, N. Y.

[1] *Journal* Society of Automotive Engineers, April, 1918.

Future of the Barium Industry*

BY WILLIAM H. ROLLIN

THE future of the barium industry, to my mind, is almost entirely dependent upon whether the Government raises a protecting tariff or not, and it seems to me most appropriate that we should proceed without very much delay so as to get our houses in order against the time when this country will have tremendous competition in those materials which we have made since the beginning of the great war. There are several contributing causes which lead me to think this.

The barium industry in this country is in its infancy and has not had time to become well established or financially strong. The makers of machinery suitable to this industry are lacking in experience and many of their products appear quite crude in comparison with some of the European machinery, and then, for some strange unknown reason, barium products have

*Read at the Chicago meeting of the American Institute of Chemical Engineers, Jan. 15, 1919.

always been manufactured on a very small margin of profit and this, in conjunction with the fact that wages in the United States are at least 100 per cent higher than in other countries, would indicate to me that, without the above-mentioned tariff wall to shelter behind, the barium industry will cease to exist in this country in the very near future.

The question of freight rates will also play an important part in determining the future importance of this industry, for we must remember that the consumer can afford to buy our goods only if they are as good in quality and as cheap as the foreign goods.

Now the tendency seems to be for our railroad freights to keep rising and I see very little hope of their being reduced, especially under Government supervision, which, as we all know, is uneconomical and more expensive than private management. On the other hand, the end of the world war leaves the shipping of the world in better shape than it ever was.

Ocean Freight War Foreseen

For the first time in many years the American mercantile marine will enter into the race as a serious competitor against Great Britain, France and Holland. I foresee in the near future an ocean freight war, which will make transportation by water extremely cheap, and if this takes place it will, of course, do its part toward annihilating the barium industry in the country, provided the industry is not given proper protection.

We have information from Europe that the various Governments there are encouraging the consolidation and amalgamation of various interests engaged in the chemical industry, purely with the idea of strengthening their position and their financial condition and putting them in a position to effect great economies in overhead expenses, all with a view toward invading the world's markets with their products and preventing, if possible, the balance of power in the chemical industry from swinging to America.

It is quite obvious that an industry of this kind, which now employs a small army of men, should be maintained and preserved in such fashion that the industry can live, and I would suggest not only tariff protection, but laws which will permit the responsible manufacturers in the same line to meet and discuss freely the costs and selling prices. On the other hand, we, in the United States, are up against the Sherman anti-trust law and numerous other laws of like character, which forbid and make criminal any effort at consolidation or co-ordination of interest and prevent any steps being taken to form the various units of the several branches of the chemical industry into any kind of a league for their self-protection and preservation.

I should, therefore, recommend as a relief and as a protection, that immediate attention be given to our needs by the legislators, and while I do not ask for an excessive tariff at once, I feel that for economic reasons we must have protection, not against Germany alone, but against those other countries which are now ready to compete under a lower wage scale and with cheaper freights.

The system of taxation to which the Government has resorted to meet the expenses incident to the great war, while no doubt very efficient as a medium of obtaining money, is, in my opinion, ill-advised in some respects, in so far as it seems to bear down with undue weight upon manufacturers in general. This pressure is felt most acutely by such new industries as our own. We find a difference between our Government and the Governments of European countries, who in an endeavor to help and stimulate their growth, in the case of many young industries, declared them to be tax-free until the time that they are financially capable of bearing their proportionate share of the country's expense.

As far as the volume of business is concerned, the barium industry is active or inactive in direct proportion to the business activity or inactivity of the country as a whole.

Barium products, including barium peroxide, barium chloride, barium nitrate, barium carbonate, barium sulphide, etc., depend for their sale on so many diversified interests that the volume of business which can be done in them is a very good index as to the general condition of business throughout the country, and the stoppage or the elimination of the barium industry would have a very deleterious effect on a great many other industries. For instance:

Barium Products Used in Many Industries

Barium peroxide is used in the times of peace for the manufacture of U.S.P. hydrogen peroxide and as a bleach, especially in the straw hat and blanket industries.

Barium sulphate (precipitated), known in the trade as blanc fixe, is used in the manufacture of automobile tires, in the paper industry, in making printer's ink, in pigments and in many other ways.

Barium sulphide, also known as black ash, is used with zinc sulphate to manufacture lithopone.

Barium carbonate has widely diversified uses in the manufacture of scumless brick, in rat poison and high grade optical glass, etc.

Barium chloride is largely used in the dye industry, is absolutely necessary in the manufacture of photographic materials and enters into the manufacture of a great many other chemical compounds.

Barium hydrate finds its largest use in the beet sugar industry.

Barium nitrate enters into the manufacture of fireworks, detonators, railroad signals and, of course, enters very largely into munition making, as well as having numerous other peace-time uses.

Sodium sulphide, while it can scarcely be talked of strictly as a barium product, is, nevertheless, available as a by-product of the manufacture of certain barium products. It is absolutely essential to the making of sulphur dyes and is the most extensively used depilatory in the conversion of hides into leather.

I have only mentioned a very few of the uses of barium products, but enough, I hope, to allow you to readily see of what importance these uses are and to give you an idea of the necessity of making conditions such that the barium industry will not perish.

To sum up: To put the barium industry on a sound commercial basis in this country we require, first, a strong tariff wall; second, reduced freight rates; third, the right to organize, and fourth, a little more consideration from the Government in the matter of taxes. Given these four items, I would say that the barium industry in the United States has a great future.

The Manufacture of Hydrocyanic Acid

Compressed Hydrocyanic Acid to Be a Commercial Commodity—Generation of the Gas for Industrial Purposes, Description of Semi-Industrial Apparatus and Plans for a Large-Scale Operation—Yields and Production Capacity

By H. A. PELTON and M. W. SCHWARZ*

HYDROCYANIC acid was produced for use in the manufacture of cyanogen chloride and for other experimental work. The problem of hydrocyanic acid manufacture may be of interest commercially in connection with the fumigation of fruit trees. At the present time most of the hydrogen cyanide employed for this purpose is prepared on the grounds from cyanide and sulphuric acid, inclosing the trees to be treated in a tent. By employing liquid hydrocyanic acid in cylinders, the trees can be treated with an attendant saving in materials, apparatus and labor accompanied by a more efficient fumigation. It is also possible that hydrogen cyanide may replace carbon monoxide and other gases in fumigating vessels.

Method Employed

The method employed, in brief, consists in adding sodium cyanide solution to dilute sulphuric acid; the water vapor in the evolved gases is removed by fractional condensation, and the concentrated hydrogen cyanide is then condensed at atmospheric pressure. To expel hydrogen cyanide dissolved in the reaction mixture, the latter must finally be brought to the boiling point. Hydrocyanic acid forms dark tars with excess of sodium cyanide, and the cyanide is therefore added to the acid and an excess of the latter over the theoretical amount is employed. The residual liquor in the apparatus after the completion of the reaction must be promptly discharged, as on cooling sodium sulphate crystallizes out. The apparatus (illustrated in Fig. 1) consisted of a 50-gal. steam-jacketed kettle, lead-lined and provided with a lead-covered agitator. The kettle was fitted with a thermometer well, inlet for cyanide solution, and bottom discharge closed by a lead-lined valve. Vapor leaves the kettle through a column, consisting of a 6-ft. length of 4-in. iron pipe, packed with large lumps of coke; the latter is supported by a perforated lead plate, placed at the bottom of the column and between the flanges so that it forms a gas-tight metallic gasket.

Apparatus Explained

The reflux condenser is mounted above the column, and consists of about 30 ft. of 1-in. iron pipe, mounted in a half barrel and cooled by ice. Vapor from the column enters the top coil of the reflux; the lower coil leads into a separator, consisting of a tee. Vapor and condensate enter at the top of the tee through a long nipple; vapor leaves through the side opening, and condensate drains from the bottom, and back to the top of the column, through a trap.

The vapor outlet from the separator is piped to the main condenser; the latter is composed of 9 turns of 1-in. iron pipe, 3 feet in diameter. The coil is mounted in a wooden tub, and cooled by cracked ice.

Condensate from the main condenser is received in a sheet-iron cylinder, 12 in. diam. x 24 in. The receiver is mounted in a barrel and provided with a bottom outlet and vent; the latter consists of a vertical length of ½-in. pipe, the upper end bearing an inverted U. A sight glass is inserted in the line between the

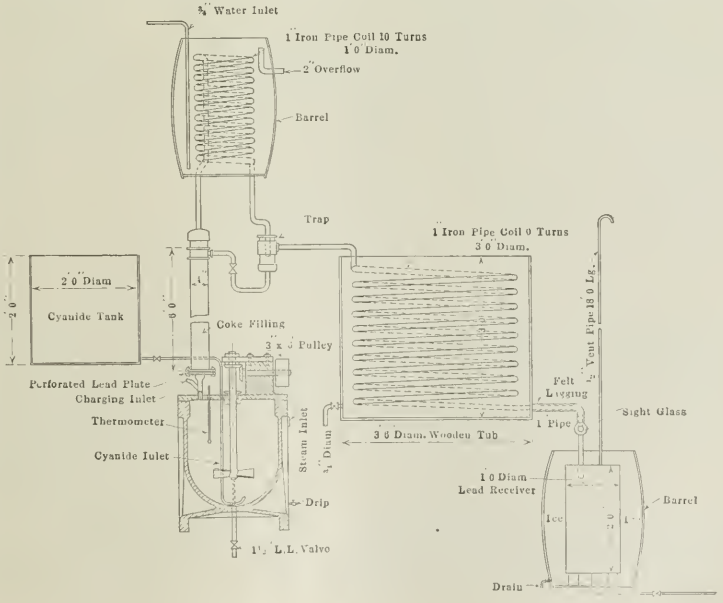


FIG. 1. APPARATUS FOR MANUFACTURE OF HYDROCYANIC ACID

*Published by permission of the Director, Chemical Warfare Service, U. S. A.

condenser and receiver. Product is charged in steel cylinder, with valves removed.

The sodium cyanide container is a sheet-iron cylindrical vessel, with bottom outlet piped to the reaction kettle.

Method of Manufacture

The kettle is charged with 54 lb. of water and 54 lb. of 66 deg. B. sulphuric acid added, bringing the temperature of the mixture to about 70 deg. C. Forty pounds of sodium cyanide (96 to 98 per cent) are dissolved in 100 lb. of warm water in the sheet-iron container, which is then covered.

The condenser, reflux and receiver are packed in ice, the agitator started and the cyanide solution run into the kettle. The addition should take from 1½ to 1¾ hours. Steam is then turned into the jacket of the kettle, and the mixture brought to the boiling point.

The approximate cost of production is calculated below:

	Cents per lb. of HCN.
Sodium cyanide at 31.5c.	74.2
Sulphuric acid at 2c.	6.4
Steam, power, ice, etc.	10.0
Labor	14.3
Overhead and repairs	2.5
	107.4

The charges for power, labor, overhead, etc., can be materially reduced if units of larger capacity are employed.

Proposed Improved Plant

Fig. 2 is a drawing of a proposed plant in which various improvements are embodied. Provision has been made for brine cooling and for more accurate temperature control.

As the stability varies with the purity of the product, a bisulphate tower has been introduced for the purpose

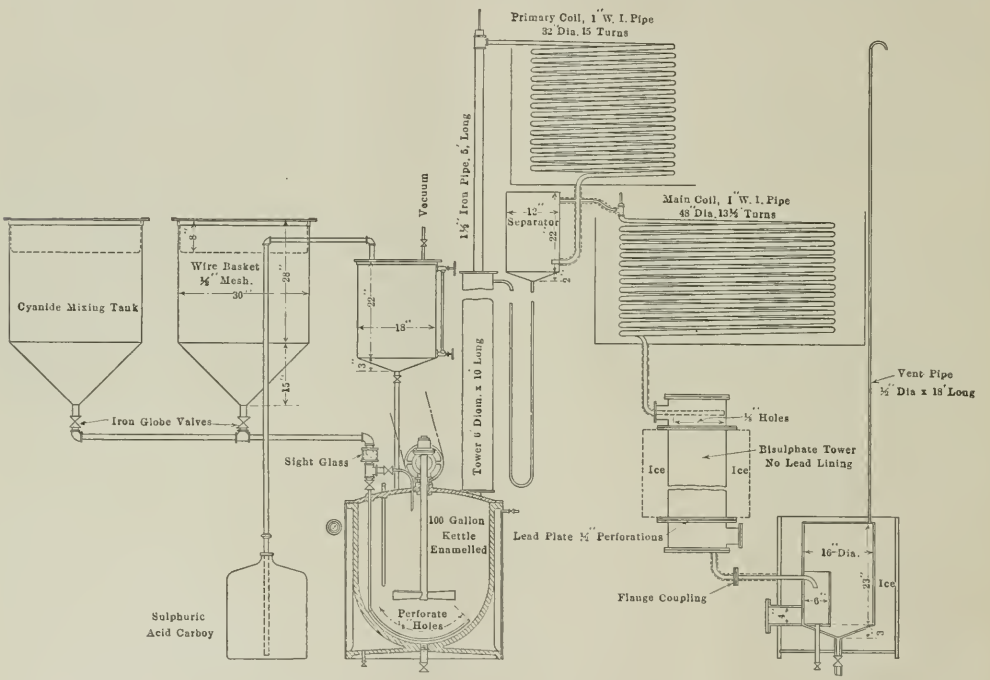

FIG. 2. A PROPOSED HCN APPARATUS

The residue is discharged while warm, and the kettle and discharge lines flushed out.

When the receiver contains a sufficient amount of product, it is drained into an open steel cylinder, previously weighed and cooled. The valve is then inserted, after applying red lead to the thread.

Yields and Production Capacity

An average yield of 78 per cent of the theoretical yield of hydrocyanic acid has been obtained. When the apparatus is properly manipulated the product runs from 90 to 95 per cent HCN. A production of 250 lb. per 24 hours has been obtained by the method herein described, and a total of 7000 lb. manufactured.

of obtaining a more anhydrous product. The receiver is designed to separate any solids carried over from the tower.

In conclusion, the writers wish to express their appreciation of the many helpful suggestions offered by Dr. James R. Withrow, and also wish to thank George O. Kildow for his assistance in the work.

This work was started under the Bureau of Mines of the United States Department of the Interior, and was continued under the Research Division, Chemical Warfare Service.

Influence of Temperature Upon the Action of Slag Upon Refractory Materials

By Raymond M. Howe*
Industrial Fellow, Mellon Institute, Pittsburgh, Penn.

DURING the present period of intense industrial activity, the linings of the various furnaces have played a very important rôle in determining their capacities. In some cases the firebrick or special shapes have given long continuous service, while in other cases the results have not been as satisfactory. As a result, there has been some contention between the consumers and manufacturers of firebrick as to the relative merits of this product, the consumers often claiming that it is not of the pre-war standard and the manufacturers maintaining that it is of equal quality. The latter maintain that the shorter life of refractories, when encountered, is often due to the more severe duty which is imposed upon their product during the struggle for an ever-increasing output of metals.

The work here presented was carried out for the purpose of determining the action of various slags at different temperatures on several standard brands of firebrick. The data secured would therefore appear to bear directly upon the question at issue, for it is well-known that a common means of increasing production consists of increasing the working temperature.

The general plan was to secure bricks of recognized quality and to test the action of several slags upon them at different temperatures. The method used for determining this action was essentially the same as is used at the Carnegie Steel Co.

Work done at that laboratory has shown that if a brick is heated to a definite temperature and thirty-five grams of slag are placed in a cavity at that temperature and are allowed to act for two hours, valuable information can be secured.

Before adopting their method certain points were checked pertaining chiefly to the influence of the time of action of, and the quantity of slag used, upon the

TABLE I—INFLUENCE OF TIME AND QUANTITY OF SLAG USED UPON RESULTS SECURED FROM SLAG TESTS

Penetration of 35 grams of slag in two hours	0.64
Penetration of 35 grams of slag in four hours	0.68
Penetration of 35 grams of slag in six hours	0.64
Penetration of 105 grams of slag in two hours	0.76
Penetration of 105 grams of slag in four hours	0.72

results secured. Tests were made in which the time and slag were trebled, but this procedure failed to produce a more pronounced action.

In reporting the results the total cross-section of the slag saturated area was first measured by means of a planimeter. The area of the original cavity was then subtracted from this. The difference represented the area of the section which had been penetrated by the slag. This area when divided by the linear surface of contact gave a value which represented the square inches of penetration per inch of contact.

The results given in Table I confirm those reported by Nesbitt and Bell and lead to the same conclusions, i.e., when a brick having a cavity 2½ inches in diameter is treated with 35 grams of slag and it is allowed to react for two hours satisfactory results are obtained. In the preceding work 35 grams of slag reacting for two hours resulted in a penetration value of 0.64. When the severity of this test was increased 600 per cent, the penetration factor increased but 12.5 per cent.

Method of Procedure

In view of this preliminary work, the following definite method of procedure was adopted:

The test bricks, each having two cavities 2½ inches in diameter by ½ inch in depth, were heated slowly to the temperature at which the test was to be made. This temperature was held for 1½ hours. Thirty-five grams of slag were then introduced and were allowed to react at this temperature for 2 hours. The bricks were then allowed to cool, were cut through the center of the cavities, and the penetration was noted in the manner previously described.

TABLE II

Slag	Blast Furnace	Heating Furnace	Basic Open Hearth	Acid Open Hearth	Zinc	Copper
Silica	37.32	34.16	18.42	46.48	34.30	28.20
Alumina	13.21	6.13	3.85	5.45	14.74	2.20
Iron	1.62	43.60	14.55	29.30	21.00	2.10

Copper	0.00	0.00	0.00	0.00	1.28	58.21
Zinc	0.00	0.00	0.00	0.00	8.20	0.00
Melting point	1220°C.	1050°C.	1275°C.	1400°C.	1025°C.	1020°C.

Six slags, which were secured from the Carnegie Steel Company's laboratory, were used during the tests. Their analyses and fusion points are given in Table II. The three bricks used are designated by *A*, *B* and *C*.

Experimental Data

By following the method already described and varying the brick, the slag and the temperature, one at a time, average results were secured as shown in Tables III to VIII.

In each case the slag penetrated more deeply into the brick at higher temperatures. In several cases an increase of 100 deg. C., or less than 10 per cent, resulted in nearly doubling the penetration.

This increased penetration has several effects in actual practice. One effect concerns the strength of the brick itself. It is a known fact that bricks when saturated with slag are not so strong at high temperatures as when they are free from slag. This decreases their ability to sustain the weight of the other parts of the furnace.

The refractories of the lining is also decreased when it becomes soaked with slag.

The lining is also subjected to more severe chemical action. This action takes place rather slowly in many cases, but rapidly in others. In any event, the action takes place sooner when the slag forces its way further into the inner portions of the lining. Being more active at higher temperatures, its solvent power is also increased.

In view of these tests, it appears very much as if the relation of output and the life of the lining is similar to the rate of driving and the life of an automobile. Cars which operate successfully for 50,000 miles when driven at the rate of twenty miles per hour give much less service when driven forty miles per

*Paper read before a meeting of the Refractories Manufacturers Association on Nov. 20, 1918.

hour. These same cars when subjected to the gruelling ordeal of a stock car race often fail to complete the first hundred miles.

Lives of Furnace Linings Must Be Compared According to a Sliding Scale

Such conditions are constantly encountered when any product is driven to its limit. Such being the case, it is not fair to compare the lives of furnace linings on the daily basis. Neither is it fair to compare them on the tonnage basis, when one furnace is worked at moderate and another at maximum capacity. Under conditions occurring with increased output, they must be compared according to a sliding scale. If a furnace is operated under such conditions that the daily output of metal is increased 50 per cent, it cannot be expected to last as long, or even two-thirds as long (during which time equal tonnage would have been secured), but from one-third to one-half as long. The consumer must realize this and balance his costs under normal production against those under increased production. If the balance is in favor of conditions of increased production, he must, if he uses the most suitable material, expect to encounter continued shorter service from linings.

Nitric Acid.—The records of the War Industries Board show that the production of nitric acid in 1918 was 634,817 tons of 100 per cent nitric acid. The Chemical Division states that no statistics regarding the production in 1916 and 1917 have been gathered.

Mesothorium Work of the Bureau of Mines

THE demand for radium for medical work, but more particularly for luminous paint, has made the question of possible radium substitutes of considerable importance. Radium luminous paint was used in the war for a number of purposes, more particularly on the dials of instruments used on airplanes, so that these instruments could be read at night; for electric push buttons, door numbers and small images for shrines, etc. The paint is permanently luminous in the dark and contains from 0.1 to 0.25 milligrams radium element to one gram of zinc sulphide. A luminous watch face usually has from ten cents to twenty cents of radium on it.

An excellent substitute for radium for certain purposes is mesothorium. This is a radio-active element found in monazite sand and other thorium minerals. When first extracted it is not in satisfactory condition for luminous paint, but must be allowed to "ripen" for several months or even a year before it can be used. During this time the alpha radiation which is required for luminous paint becomes sufficiently strong. On the other hand the beta and gamma radiation of mesothorium grows rapidly and it can be used for medical purposes within a few days after preparation.

Radium has a long life, half of it decaying in approximately 1600 years. Mesothorium on the other hand has a short life, five or six years being its useful life for luminous paint purposes. The price in the past has varied from 40 to 60 per cent of that of radium, the comparison being on products of equal activity. For medical purposes therefore it cannot compete with radium as long as there is plenty of the latter; for luminous paint, to be used on objects which themselves have a short life, it is an excellent substitute for radium.

Shortly after the United States entered the war the Bureau of Mines made a co-operative agreement with the Welsbach Co. of Gloucester, N. J., for the study of methods of extraction and recovery of mesothorium. The work was carried on at the Rocky Mountain station of the Bureau of Mines at Golden, Colo., under the direction of Dr. R. B. Moore, superintendent of the station, Dr. Herman Schlundt being assigned to the detailed work on the problem. Successful methods of extraction and recovery have been worked out and connected up with the regular metallurgical processes of the Welsbach Co.

The next largest producers of thorium salts in the country about the same time became interested in the recovery of mesothorium and worked out its own methods. Consequently at the present time mesothorium is recovered from practically all the monazite sand treated in the United States.

The details of the work of the Bureau of Mines will be published later. A preliminary announcement was made by Dr. Moore in a paper given at the September meeting of the American Institute of Mining Engineers at Colorado Springs. Incorrrect press reports of this announcement gave rise to some serious misstatements of facts, hence this statement.

The Bureau of Mines has never claimed the discovery of mesothorium, as this element was first identified and described by Hahn in 1905.

Flotation of Oxidized Ores of Lead

Process of Sulphidizing Ores Such as Cerussite, Wulfenite and Cerargyrite — Sulphidizing Agents — Pyrolusite and Other Interfering Elements — Flotation Oils and Results — Consumption of Sodium Sulphide

By GLENN L. ALLEN

IN THE dressing of lead ores a greater recovery of the oxidized minerals is becoming more and more urgent. Concentration of the coarser particles of oxidized minerals of lead usually offers no difficulties not readily met by the time-honored gravity methods, but the recovery of the slime values is often a more difficult problem. Due to its friable nature, the principal oxidized lead mineral, the carbonate, readily finds its way into the slime during crushing and the usual subsequent treatment with jigs and tables. The milling of this carbonate or the mixed carbonate and sulphide ore is therefore almost invariably attended with a serious loss of lead and often of silver in the slime.

In view of the fact that the concentration of the simple sulphide minerals of lead is meeting with success in many flotation mills, it is only natural that the metallurgist should strive to adapt the process to the recovery of slimed oxidized minerals. Gratifying results have been obtained by the use of the ordinary froth-flotation in connection with the sulphidizing process. This is a simple process entailing the use of a small quantity of a commercial chemical, sodium sulphide, or its equivalent.

The Sulphidizing Process

Since the sulphidizing idea is new to many, a brief description of the process, its use, agents and methods may be of value. The process, as applied to lead ores, was tested on a laboratory scale by the Salt Lake City station of the United States Bureau of Mines,[1] to which belongs much credit for directing attention to the possibilities of the process. The writer has since developed and perfected the idea for use on the oxidized lead of the Shattuck-Arizona Copper Co. at Bisbee, Ariz., and the milling data hereinafter given are results of this work.

Sulphidizing is the process of altering oxidized minerals to the sulphide form, at least superficially, to produce a product recoverable by flotation. It consists simply in subjecting the carbonates to be floated to the action of a soluble sulphide such as sodium sulphide. The sulphur molecule of the reagent exhibits a rather remarkable avidity for the lead in the cerussite, and, if the mineral is clean, almost instantly forms a superficial film of lead sulphide on the carbonate particle. This black film is very firm and even exhibits a sub-metallic luster when viewed under the microscope or on the vanning plaque. The amount of sulphidization may vary from a thin film to a complete conversion of the particle. The desired degree of conversion depends on the ore itself and is best determined by actually sulphidizing the ore and then testing it for flotation. In practice, the amount of reagent supplied to an ore is not necessarily a measure of the degree of sulphidization, because elements other than lead in the ore may destroy the usefulness of the sodium sulphide.

With alkaline sulphides, such as of sodium, another factor limits the amount allowable in practice in the flotation pulp, that factor being the alkalinity due to hydrolysis of the sulphidizing agent. Excess alkalinity produces a very bad physical effect on the flotation, but so far as noticed is not detrimental to sulphidization of lead carbonate ores. In the case of sodium sulphide, hydrolysis is said to be nearly complete:

$$Na_2S + H_2O = NaOH + NaHS.$$

Thus for every pound of Na_2S dissolved in the flotation pulp, theoretically about half a pound of NaOH is introduced. Using increasing amounts of Na_2S, it is evident that a point would soon be reached at which the alkalinity would be detrimental to flotation. This is borne out in practice, and the point at which flotation begins to fail is so marked as to be easily detected by the operator. This maximum allowable alkalinity varies with the pulp conditions, especially with the kind and quality of oil used. For example, when treating 5 per cent lead ore in a pulp containing 30.2 per cent solid and using 1.15 lb. of oil per ton of dry feed, the upper and lower limits of sodium sulphide consumption were found to be respectively 3.5 and 1.3 lb. per ton of dry ore. Below 1.3 lb. the froth was lean in lead—probably due to insufficient sulphidization of the carbonate—while on passing 3.5 lb. the froth flattened, dropped its mineral and broke to water, due to the excess alkali. The mixture of oil used consisted of Cleveland Cliffs wood creosote 25 per cent, crude coal-creosote 64 per cent and Pensacola tar and turpentine No. 350, 11 per cent.

Returning to the hydrolysis equation, it would incidentally appear that the $HS^=$ radial is the active sulphidizing agent in this case. In the flotation of cerussite, the chemical action of NaOH may even be beneficial, due to the solubility of lead carbonate in NaOH solution. The exact chemistry of sulphidizing yet remains to be stated. In keeping with the empiricism of flotation the important fact nevertheless remains that the carbonate, once sulphidized, floats almost if not quite as readily as the natural sulphide.

Sulphidizing Agents

Possible agents for use as sulphidizers are elemental sulphur, sulphuretted oils, hydrogen sulphide, various sulphur compounds of sodium and calcium (such as CaS, $Ca(SH)_2$, CaS_6, Na_2S, NaHS, Na_2S_5, Na_2S_x), and

[1] "Flotation of Oxidized Ores." Ralston and Allen. Circular of the U. S. Bureau of Mines, May, 1916.

similar soluble sulphides of other elements. From the practical and commercial standpoint H_2S and Na_2S appear most important at the present time. Both of these are efficient sulphidizers; they are cheap, commercially obtainable, reasonably safe, and not mechanically difficult to handle. Making a comparison, H_2S is probably cheaper and easier to prepare at the mill, is a narcotic poison and is a more active sulphidizing agent, a property not as desirable as at first might be supposed, especially in treating lead ores. Due to its greater chemical activity, however, it is thought to be better for silver. Sodium sulphide, on the other hand, is obtainable normally in car lots at about 2c. per lb. at the factory for 60 per cent Na_2S, is convenient and safe to use, has less available sulphur per unit and when used in excess produces undesirable conditions in the flotation pulp. Being less active chemically than H_2S, it does not so readily attack and sulphidize iron compounds, especially limonite, which so often occurs with lead carbonate. Thus the use of Na_2S often tends toward cleaner concentrates both in iron and insoluble contents. Sodium sulphide is a depilatant, softens the finger nails and its dust is very irritating to the skin and nostrils. It is not dangerous to handle even in quantities if the men are properly protected.

In general, either agent probably could be made satisfactory for most ores through careful adjustment, while the choice of agents would depend on the ore itself and on local conditions. The value of $Ca(SH)_2$ and of oils distilled with sulphur for use as reagents, however, is not to be overlooked.

Methods of Sulphidizing

Most lead ores will sulphidize either wet or dry. The use of a gas on dry, finely divided ore, however, does not appeal to the mill man. As most slime subjected to flotation is produced by wet crushing and grinding, the introduction of a soluble sulphide into the mill circuit appears to be the most practical way of sulphidizing. The use of H_2S gas, however, has been found entirely practicable; for the best results it should be introduced into a thick pulp and the pulp diluted before going to the flotation cells. This procedure eliminates the evil effects of excess H_2S and insures a more satisfactory sulphidization of the ore.

Wet sulphidizing was practiced exclusively in the mill tests on ore from the Shattuck-Arizona Copper Co., with which this paper deals in particular. The fused sulphide was dissolved and stock solution made up to a definite strength, usually between 3 and 5 per cent Na_2S by weight. During the course of the experimental work the solution was added successively to the pebble mill grinding the flotation feed (see Fig. 1), to the pebble mill's drag classifier, to the launder leading from the classifier to the dewatering cones, later to the suction of a centrifugal pump elevating the flotation feed to a Saffold agitator just ahead of the flotation cells, and finally to the cells themselves.

As the point of adding the sulphide progressed toward the flotation cells the time of contact between the reagent and the ore necessarily decreased. The time element was at first thought to be an essential factor, but proved to be relatively unimportant in treating this particular ore. Satisfactory sulphidization was obtained at all periods, as the time of contact between sulphide solution and ore was varied from twenty minutes before entering the flotation cells to zero when adding the solution directly to the head of the cells.

Intimate Mixing Necessary

An essential to sulphidize the ore in hand appeared to be a sufficiently intimate mixing of the dilute sulphidizing solution with the thickened ore pulp, in order to insure a sulphide coat for every particle of carbonate. A sufficient amount of reagent, of course, had to be available in the pulp. It is thought, though, that an appreciable period of time should be allowed for sulphidizing, such being both beneficial and desirable, especially when the limonite content of the ore is relatively high. As the solid in the flotation feed often contained 25 per cent iron, a variable portion of which was limonite and the remainder specularite, it proved a little safer and more satisfactory to add the sulphide to the Saffold machine just before the pulp went to the flotation cells. The Saffold agitator served the double purpose of assisting in sulphidizing the pulp and at the same time thoroughly incorporating the oil. The latter advantage of the use of the preliminary agitator was somewhat more apparent when using more than 1 per cent of oil.

Sulphidizable Lead Minerals

Cerussite and wulfenite sulphidize very readily. Minium, anglesite and pyromorphite slowly tarnish to a dull black in strong solutions of Na_2S, but in practice poor recoveries are made on these minerals by sulphidizing and flotation. Vanadinite and descloizite are very indifferent toward sulphide and therefore float poorly.

Cerargyrite, commonly called horn-silver, often is associated with oxidized lead and fortunately sulphidizes very readily. It is then easily recovered by flotation, concentrates as high as 2000 oz. per ton having been made in small operations. The bromide of silver also sulphidizes readily.

Interfering Elements

Certain elements, if present in the ore or associated with the lead in any way, greatly interfere with the sulphidizing operations. Probably the most important of these is manganese—especially in the form of pyrolusite—because of its oxidizing influence on the sodium sulphide. Unfortunately this mineral often is found with oxidized lead ores and is furthermore usually found in the slime portion of the mill pulp. This necessitates a separate treatment for primary and secondary slime or a great dilution of the primary with the secondary slime before satisfactory sulphidizing can take place. The soft, velvety variety of pyrolusite is probably the worst offender. Ralston and Laney of the Salt Lake City station of the U. S. Bureau of Mines have determined that compounds of manganese, basic sulphates of iron and peroxides of lead all destroy sodium sulphide. Ferrous salts in solution are classed as undesirable along with those just mentioned

because they too consume Na_2S in their precipitation as ferrous sulphide. (Sodium sulphide, being the salt of a weak acid, is highly dissociated and therefore precipitates ferrous sulphide.)

Types of Ores Suited to Sulphidizing

As with most other metallurgical processes, no hard and fast rules can be laid down as to which ores are amenable to sulphidizing and flotation. In general, those with silica and iron as the chief gangue constituents in preference to lime and alumina are likely to prove more docile. Even low percentages of manganese are very undesirable, if not prohibitive, as would be any of the other deterrents named above. Kaolinized ores are sometimes rebellious to sulphidizing and flotation, probably more through their physical effect upon the flotation than due to their chemical effect on the reagent.

The Southwest contains several lead deposits in which cerussite is the most apparent mineral, but along with this carbonate occurs variable amounts of lead in the form of pyromorphite, minetite, vanadinite or descloizite. These ores give poor returns by sulphidizing alone, and gravity and flotation usually give undesirable mixtures of little commercial value in the concentrate.

It has been said that ores high in iron would not sulphidize commercially, but such has not proved to be the case. Ores carrying most of their iron in the form of limonite of the yellow ochre variety are usually difficult to handle both from a physical and chemical standpoint.

TABLE I. LACK OF RELATION BETWEEN ANALYSES OF OXIDIZED LEAD ORES, AND THEIR FLOTABILITY

Ore	Au	Ag	Pb	Insol	Fe	S	Mn	CaO	CO_2	Al_2O_3	Zn	Remarks
1	0.02	5 8	23 9	64 7	2 5	0 0	0 0	0 1	...	.	.	Excellent recoveries by sulphidizing.
2	0 02	8 4	10 7	42 6	30 0	Tr.	.	Tr.	..	Tr.		Excellent recoveries by sulphidizing.
3	0.14	15 4	34 5	41 2	7 9	1.3		1 1	.	.		Sulphidizing failed entirely.
4	0 03	102 3	7 6	78 3	5 6	0.0	0.0			.	.	Excellent recoveries. Very little CaO and Al_2O_3. Silver in form of AgCl.
5	0 12	0 5	28 3	.	..	..	.	..	.	.	.	Poor results. Ore contained 6.1 per cent V and 8.3 per cent Cu in Cuprodescloizite.
6	0.18	15.9	4 2	73 9	1 1	0 2	0 4	4 7	5 2	4 4	7.0	Poor results by sulphidizing.
7	..	1 3	9 0	60 4	16 3	0 4	.	2 7	1.8	7 6	0.9	Excellent recoveries by sulphidizing.
8	0.01	17.9	16 5	43 3	5 3	3 2	..	3.2	2 3	21 6	5 4	Poor recoveries. Part of the lead in form of sulphide.

The chemical analysis of an ore is of little value in determining its amenability to flotation, unless it discloses interfering elements or suggests unsulphidizable compounds of lead or silver. Table I exhibits the analyses of some ores interesting in this aspect.

Legal Status of Sulphidizing

Sulphidizing, like most other metallurgical ideas, is not new. Commercial application of the idea is now being made by metallurgists who seek to increase the recovery of oxides by flotation. A complete review of the patent literature on sulphidizing, fully crediting each inventor, has been published by Rickard and Ralston.[2] Reading between the lines of this book it appears that there is no American patent covering sulphidizing with froth-flotation whose validity is not questionable.

Mill Test on Shattuck Ore

About 1000 tons of oxidized lead ore from the mine of the Shattuck-Arizona Copper Co. was concentrated during the sulphidizing tests to be described. The ore occurs in the form of a siliceous breccia, and, naturally, silica is the chief gangue constituent. Iron, mostly in the form of a black, crystallized specularite, together with variable amounts of limonite, is the other most important gangue mineral. Manganese in appreciable quantities has not been detected; lime and alumina occur only in very small amounts, and the sulphur content varies from a trace to 0.4 per cent.

Cerussite, cerargyrite and gold are the valuable minerals. The lead is practically all in the form of the carbonate, but with small amounts of the sulphate present. So far as known at present, the silver occurs in the form of the common chloride. In view of the fact that high recovery of the silver by sulphidizing was difficult to obtain and of the further difficulty of extracting this silver with hypo or cyanide, the writer has suspected at times the presence of some other form of silver.

The gold, silver and lead are apparently in no way associated or combined. The valuable minerals are of considerably greater specific gravity than the gangue, so the mineral particles larger than 200-mesh when free from gangue are readily concentrated by gravity methods. The average daily chemical analysis of the ore was: Au, 0.054 oz. per ton; Ag, 5.86 oz. per ton; Pb, 11.39 per cent; insoluble, 64.12 per cent, and Fe, 12.80 per cent.

Preliminary Laboratory Tests

Prior to the mill tests, a great many laboratory experiments were made on samples systematically taken throughout the workings in the lead orebody. Each mine sample was dried, crushed and reduced to from —80 to —200 mesh in a disk pulverizer. In a few cases the fine grinding was done in a laboratory-sized ball mill. At first the 500-gram samples used for each test were charged into agitator bottles with solutions of sodium sulphide. This chemical was used in the proportion of 6 to 12 lb. per ton of ore treated.

As the experimental work progressed the preliminary treatment was discontinued and the sulphidizing accomplished directly in the flotation cell. The dry, pulverized ore was placed in the cell with sufficient weak sulphide solution, and water added to make a pulp of 50 per cent solid. One minute of sulphidizing agitation was given before adding the oil for emulsification. After oiling the sulphidized pulp, the test machine was filled with sufficient water to make a pulp of about 25 per cent solid and the test completed in the regular manner, making both the roughing and cleaning operations on the same sample. A Janney test machine was used in the laboratory work.

[2] "Flotation," Rickard and Ralston, p. 360.

A comparison of laboratory and test mill results usually is of interest. In this case the test mill returned slightly better metallurgical results than the laboratory machines and used only about one-third the amount of Na_2S needed in the laboratory. The oil consumption also was very much less in the mill than in the laboratory. The small-scale tests, however, were very satisfactory. They clearly indicated that the finely ground ore was amenable to the proposed process and justified investigation on a commercial scale.

The Test Mill

The experimental concentrator of the Phelps-Dodge Corporation at Bisbee, Arizona, was used in making the mill tests. The flow-sheet of this mill at the time of making the tests is shown in Fig. 1. The mill was equipped with a No. 5 Telsmith gyratory breaker set to deliver ore crushed to pass a 1.5-in. ring. A Challenge feeder delivered the crushed ore to an 18-in. conveyor belt, which carried the ore over an automatic weigher to a 5-mm., round-hole trommel in closed circuit with a set of 16 x 36-in. rolls. Water added to the trommel carried the unclassified 5-mm. undersize from the trommel direct to Butchart roughing tables. The table concentrate was finished direct to the concentrate bin and the tail was dewatered in a drag

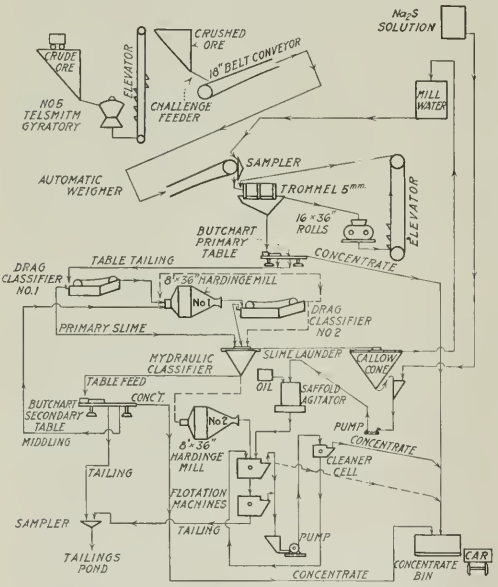

FIG. 1. FLOW SHEET OF EXPERIMENTAL CONCENTRATOR

dewaterer. Most of the primary slime was thus separated from the rest of the ore by the drag and sent through a cone hydraulic-classifier to Callow settling cones to be thickened for flotation or Senn vanner feed. The sand from the drag-dewaterer passed to an 8-ft. x 36-in. Hardinge pebble mill discharging to the cone hydraulic-classifier. The classifier sand was sent either to fine-sand Butchart tables or to another 8-ft. x 36-in. Hardinge pebble mill discharging direct to the flotation cells. The flotation section was equipped with a 10-ft. and an 8-ft. rougher and one small cleaner cell, all of the K. & K. type, and a preliminary mixer or agitator known as the Saffold machine. The ore at the head of the mill, the general concentrate mixture and the general tails of the mill were all sampled automatically. The concentrates, after sampling, were dewatered in rectangular settling tanks.

Development of Process

After the primary tables, grinding mills and desliming classifiers had been tested and adjusted to suit the requirements of lead milling, the treatment of the slimed carbonate was attempted. Even the first days of sulphidizing were quite successful in spite of the fact that far too much sodium sulphide was used and that suitable flotation oils were not available. The advantages of using less sulphide solution than in the laboratory were soon discovered. Thereafter the steps in the developing and simplifying of the process consisted mostly in selecting successively more advantageous places and methods of introducing the sulphidizing solution into the mill circuit.

At first the solution was added in excessive amounts to the feed end of the first or No. 1 Hardinge mill, as high as 15 lb. Na_2S per ton of ore being used. The mill was placed in closed circuit with the No. 2 drag-classifier, to which was sent the primary slime from No. 1 classifier. This closed circuit was made with the idea of sliming everything to flotation and at the same time giving sufficient opportunity in the pebble mill and its classifier for sulphidizing the carbonate in the primary slime as well as that in the re-ground material from the mill. All-sliming had to be given up because the pebble mill would not reduce the hard quartz in the ore to such fine sizes as required for flotation. As an expedient, the product of No. 1 Hardinge mill was deslimed in the No. 2 drag-belt, the fine sand sent to secondary tables and the primary and re-ground slimes united and sent to the Callow settling cones to thicken for flotation. The pulp in both the Hardinge mill and the No. 2 classifier, however, was found to be well sulphidized. The excess alkali due to the large quantities of Na_2S used was removed from the circuit by decanting the Callow cone overflow. The thickened product of the cones was then found to float quite satisfactorily. In this system the fine sand was being sulphidized in the mill and classifier and then sent to tables. This, of course, caused an unncessary waste of reagent, so the sulphidizing solution was added to the slime after it had been delivered from the hydraulic classifier to the launder leading to the settling cones.

The fine sand as delivered by the drag classifier contained so much slime that the secondary tables failed to make the desired recovery, so the use of the drag was discontinued. Instead, the product from No. 1 mill was combined with the primary slime and sent to a hydraulic desliming classifier, and the sulphide solution was added to its overflow. This move reduced the time of contact of the reagent with the ore, but flotation continued to give good results even with the sulphide reduced to 7 lb. a ton.

The large amount of Na_2S being used rendered the overflow from the Callow settling cones unfit for reuse in the mill circuit, so the sulphidizing solution

was next added to the spigot discharge of the settling cones. With some readjustment of oils, pulp densities and a decided reduction in the amount of Na_2S, the flotation cells continue to give a good account of themselves.

Sodium sulphide solution was added to the inlet of the Saffold agitator with satisfactory results and finally carried down the flow sheet and added directly to the flotation cells. Although good results were obtained here, the cells required somewhat closer attention and their work appeared to turn on rather fine points as to alkalinity, oils, pulp density, etc. It was evident that more consistent results could be obtained by adding the sulphide to the discharge of the Callow cones, thus allowing a few minutes' contact and insuring a thorough mixing of the pulp with the weak sulphidizing solution before reaching the flotation cells. This arrangement permitted the sulphidizing reaction to occur before the oil was added to the pulp. Such would seem to be the logical sequence, but satisfactory flotation was obtained consistently while the sulphide and oil were added simultaneously to the Saffold machine.

Flotation Oils

The oils used in flotation were for the most part mixtures of hardwood and coal creosotes with small amounts of pine or pine-tar oils in addition. With frothing creosotes no pine oil was needed. While some oils and oil mixtures did better work than others, the choice of oils was not a critical part of the process. Once the sulphidizing and flotation practice was established with experienced operators, quite a variety of oils could be used with very similar metallurgical results. An oil mixture on which much of the work was done consisted of Cleveland Cliffs wood creosote No. 1, 25 per cent; Barret creosote No. 609, 64 per cent; and Pensacola Tar & Turpentine Co. No. 350, 11 per cent. About 1.2 lb. of the mixture was used per ton of dry ore in the flotation feed. Even coal tar and fuel oil were included in some of the mixtures with satisfactory results. Good results were obtained by the use of from 17 to 20 lb. of oil of the following composition:

	Per Cent
California fuel oil	79.2
Barrett creosote No. 609	9.4
Cleveland Cliffs creosote No. 1	5.7
General Naval Stores C-15	5.7

Many other oils and combinations of oils would no doubt have given just as good results. With most oils a large flow of sulphidizing solution called for more oil, and conversely over-oiling could be remedied by increasing the flow of sulphide.

Mill Results

About 30 tons of ore were treated per day at the rate of 130 to 150 tons per 24 hours. The rate of treatment was limited for the most part by the pebble mill's ability to grind the tailings from the primary tables. The concentrator operated one shift of 8 hours per day, but considerable time was consumed in making repairs and changes incidental to experimental work and in starting and stopping the mill. The daily sampling, both automatic and hand, was not begun until all adjustments had been made and the machines appeared to be doing their best under the conditions imposed on them for the particular test in hand.

The average of the daily work of the general concentrator under a variety of conditions tested in a month is exhibited in Table II. Table III gives the results of a typical day's work but on a rather high-grade head. The concentration ratios and the percentage weights were calculated on the lead assays because the gold and silver values were difficult to sample and assay accurately.

Work of Primary Tables

The Butchart primary tables gave a very satisfactory performance both in point of recovery and capacity. A single table satisfactorily handled 150 tons of —5 mm. feed per 24 hours, recovering 55 to 70 per cent of the total lead and about 45 per cent of the silver in its feed. This was crushed by rolls to pass a 5-mm. round-hole trommel and was neither deslimed nor classified before going to the table. From 8 to 16 per cent of the primary table feed was —200 mesh. The tables were equipped with Butchart progressive pitch riffles $\frac{9}{16}$ in. deep at the feed-end, sloping to $\frac{5}{16}$ in. at the concentrate discharge end. The tables were set for a $\frac{3}{8}$-in. stroke and made 275 strokes per minute. The average work of the primary tables is exhibited in Table II.

Work of the Secondary Tables

The secondary or fine-sand tables accounted for 9.1 per cent of the total lead in the original ore delivered for a month to the head of the mill, and 80 per cent of the gold, 47.5 per cent of the silver, and 71.6 per cent of the lead in their own feed. They handled from 40 to 60 tons of fine, deslimed sand per 24 hours, the spigot product of a hydraulic classifier. The average feed to these tables for a month contained 0.05 oz. Au, 4.9 oz. Ag, 4.38 per cent lead, 78.4 per cent insoluble and 9.6 per cent Fe. From 5 to 8 per cent of this feed was —200-mesh slime which should have been removed by the desliming classifier. The tables did good work on the fine sand but of course did not recover anything from the —200-mesh slime.

The table middling, containing about 0.05 oz. Au, 5 oz. Ag, 4 per cent Pb, 68 per cent insoluble and 17 per cent Fe, was returned to the Hardinge mill.

The greatest silver loss on the secondary tables was in the +48- and +65-mesh sizes, indicating that finer grinding might free more silver and thus help the recovery. The average daily work of these tables is shown in Table II.

Flotation Results

Flotation recovered about 20 per cent of the total Au, 6 per cent of the Ag, 15 per cent of the Pb, and 8 per cent of the iron in the original ore as delivered to the mill. The flotation section was equipped with two K. & K. machines with 8-ft. x 28-in. and 10-ft. x 28-in. rotors respectively, and during the latter part of the experimental work with a special cleaning cell with a 4-ft. x 12-in. rotor. The two large machines in series satisfactorily handled 127 tons of dry feed per 24 hours and averaged about 50 tons with an attendant recovery of 84.5 per cent of the Pb, 41 per cent of the Ag with 77 per cent of the Au in their own feed.

One 10-ft. machine alone handled 50 tons in several tests but the tails consistently assayed a few tenths per cent of lead higher than when two machines were running in series. Even with a large reduction in tonnage one 10-ft. machine alone would not produce as low a tail.

The 4-ft. cleaning machine appeared to raise the grade of the combined concentrates from the two roughing machines about 10 points without affecting the tailing loss of the second machine in the series. The concentrate from the first rougher in series was usually sufficiently high-grade so that it did not require cleaning. In most of the tests only the froth from the second machine in the series was retreated in the cleaner.

The feed to the flotation machines was 97 per cent —200 mesh. It contained between 4 and 5 per cent of Pb, 2 to 3 oz. Ag per ton, 16 to 21 per cent of Fe and about 62 per cent insoluble. About half of this silver was recovered and no more silver was recovered after a strong sulphidizing treatment than after a weak one. Just why a higher recovery of the silver by flotation was not obtainable has not been determined. Senn vanners and slime tables failed to make any further recovery of either silver or lead from the flotation tail.

The finished flotation concentrate under the best conditions was quite clean. One day's work, for example, assayed 0.10 oz. Au, 10.2 oz. Ag, 65.1 per cent Pb, 3.5 per cent insoluble and 5.9 per cent Fe. Especially during the early part of the testing no special effort was made to obtain high-grade concentrate from the flotation cells. The daily average of all tests made during one month is shown in Table II. This average, of course, includes many days on which unfavorable conditions were imposed on flotation purely as a matter of experiment. Table IV shows the work of flotation under different conditions.

In one test an attempt was made to slime the entire tail of the primary tables by two-stage grinding in two 8-ft. x 36-in. Hardinge mills. The use of the secondary tables was discontinued. Their usual feed was reground and sulphidized in the second mill, then discharged directly into the first flotation machine in the series along with the primary slime and that produced by the first Hardinge mill. The discharge of the second mill contained 6.3 per cent +65 mesh and 54.3 per cent —150 mesh. The results of flotation for the day are shown in Test 5, Table IV.

Chemical Consumption

The usual consumption of 100 per cent Na_2S per ton of dry slime treated by flotation was about 2.6 lb., ranging from 1.5 to 15 lb. With 4.5 per cent lead ore, 2 lb. usually gave good results. In terms of the commercial 60 per cent Na_2S this would be equivalent to 3.3 lb., costing about 10c. with cheap sulphide, or about 17c. with sulphide at war prices. Sodium sulphide sells in normal times for about $1.85 per 100 lb. of 60 per cent Na_2S f.o.b. factories in the East. At present, from $3.00 to $3.50 per 100 lb. in car lots is asked in New York and on the Pacific Coast. Thus the cost of sulphidizing need not exceed 17c. per ton even under unfavorable conditions. The manufacture of Na_2S at the mill is not at all impossible under favorable conditions, but in this respect H_2S probably has the advantage.

Rapid and accurate analytical methods based on iodometry have been developed for the control of sodium sulphide solutions. A cheaper means of control is afforded by the use of hydrometers, following the practice of alkali manufacturers.

For each pound of lead carbonate recovered about 0.02 lb. Na_2S was consumed. Theoretically 0.29 lb. Na_2S is required to convert completely one pound of lead in the form of carbonate to the sulphide PbS. At the rate of 2.6 lb. Na_2S per ton of 5.92 per cent lead ore with 84.8 per cent recovery, it may be calculated that only 6.9 per cent of the theoretical Na_2S suffices for sulphidizing for flotation on a favorable ore. It is obvious that the sulphide coating produced on the carbonate particle must be very superficial under the conditions just given, which were those obtaining in the test mill. Even with its very thin coating of sulphide the carbonate was a brilliant blue-black. The concentrate coming from the flotation machines appeared much the same as a rich galena concentrate. The black appearance of the froth changed to a dull maroon color when the ore in the pulp contained much iron, but the grade of the concentrate remained much the same. About 99 per cent of the concentrate from the flotation cells was —200 mesh. Operation of the cells was easier and low tails were more consistently obtained on feed consisting of all —200-mesh material than on pulp containing mixed sand and slime.

Future of the Process

Sulphidizing is not offered here as a panacea for all lead carbonate troubles. On the contrary it has failed almost completely in some instances, due either to elements interfering with the sulphidizing, to difficulties inherent to flotation, or to both.

For ores consuming or destroying relatively large amounts of chemicals, cheap reagents must be had if the process is to be commercial. The manufacture of H_2S from oil and sulphur is a step in this direction. Other methods for the production of sulphidizing agents are being investigated. Combinations of reagents offer possible advantages in some instances and sulphidizing in combination with leaching and precipitation methods offers possibilities.

Although doctors disagree as to the probable application that sulphidizing will have in ore dressing, one thing is certain—the last word has not been said.

Shattuck-Arizona Copper Company,
Bisbee, Arizona.

A waterproof coating for airplane propellers, which incorporates thin aluminium leaf in the finish, was developed by the Forest Products Laboratory at Madison, Wisconsin, and placed in production by the War Department. The process is practically 100 per cent effective in preventing absorption of water, particularly in the storage stage. A French authority states that 80 per cent of the French propellers produced are rejected by the pilots mainly because they are out of balance. This difficulty is due largely to unequal absorption or distribution of moisture and can be greatly reduced by an effective waterproofing coating.

Fuel Economy in the Boiler House—I

Study and Importance of the Heat Losses in Boiler Plants and Their Control — Automatic Flue Gas Recorders and Details Regarding Gas Sample Conduits, Tubes, Stopcocks, Soot Filters and Water-Jet Pumps

By JOHN B. C. KERSHAW

THE call for efficiency in the working of steam boilers was never more urgent than at the present time, when the outlay upon fuel forms such an important item of manufacturing costs in all our staple industries. Whatever the basis of the political settlement may be, the end of the war will not mean a return to the status quo ante with regard to fuel, and it is in the highest degree improbable that coal mined in Europe and America will ever return to its pre-war low level of value.

The subject of fuel economy will therefore not cease to be of importance when the war ends, but will remain equally urgent in the strenuous years of industrial competition that are ahead. Power users, consequently, both on grounds of personal profit and public interest, ought to study the question of fuel economy in the boiler house, for it is here that the greatest waste of fuel is occurring in connection with manufacturing industries.

Heat Losses in the Boiler Plant and Their Control

Figs. 1 and 2 are curve diagrams, showing the various heat losses in two typical boiler plants, both burning the same fuel—a bituminous slack testing 13,500 B.t.u. —one badly managed and the other well managed. From these diagrams it can be seen that the heat units carried away by the waste gases account for the larger proportion of the loss in both cases and that the best chance for reducing this loss lies in the strict control of the temperature and volume of these escaping gases.

The importance of the regular testing of the waste gases passing away from boiler plants lies in the fact that only by chemical tests can one judge of the dilution of the gases and whether a great excess of air is being

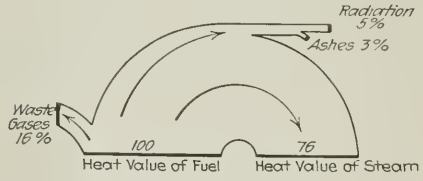

FIG. 1. EFFICIENCY DIAGRAM FOR A WELL MANAGED BOILER PLANT

passed through the furnaces. If no tests are made, the engineer in charge of the plant is absolutely in the dark as to the course of the combustion process. The waste gases, however, carry with them to the chimney a large proportion of the heat energy of the original fuel, and if the volume of these gases be unnecessarily increased, the proportion of heat lost in this way is doubled or even trebled. Efficiencies of 70 per cent and over can be attained in the boiler plant only when the heat losses in the waste gases have been reduced to a minimum (1) by cutting down their volume and (2) by reducing their temperature to the lowest point compatible with the maintenance of the required draught at the base of the chimney.

As regards the percentage of heat that may be quite easily lost with the gases escaping to the chimney with varying percentages of carbon dioxide, the following table is instructive:

Percentage of CO_2 in Waste Gases	Percentage of Heat Lost — Temperature of Waste Gases		
	400 Deg. F.	500 Deg. F.	600 Deg. F.
4	32 40	40 50	48.60
6	21 80	27.30	32 80
8	16 40	20 80	24.90
10	13 40	16 80	20 20

The losses range, therefore, from 13.4 per cent of the total heat (which may be regarded as the minimum possible when natural draught is used) up to 48.6 per cent, or nearly one-half the heat produced by combustion of the coal.

It may be objected that the latter limit is seldom reached in practice. The writer has made many tests upon boilers worked without scientific control, the exit gases from which showed only 4, 5 and 6 per cent CO_2, and he is convinced that heat losses to the chimney equivalent to one-third of the fuel burned in the boiler furnaces are quite common in practice. The scientific control of boilers, therefore, demands regular and systematic examination of the waste gases.

Automatic CO_2 Recorders

It is now about fifteen years since automatic CO_2 recorders first made their appearance. For a time they

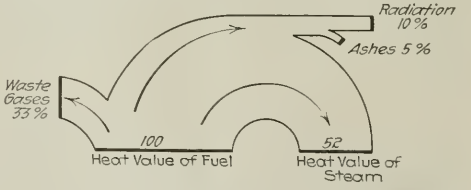

FIG. 2. EFFICIENCY DIAGRAM FOR A BADLY MANAGED BOILER PLANT

enjoyed great popularity, and were to be found in all boiler houses where the engineers prided themselves on being alive and up to date. The difficulties met with in keeping the apparatus in good working order, however, were considerable, and as the recorders failed to satisfy the demands made upon them, they were discarded by many engineers who at first were most loud in

their praise. Their failure was due not so much to defects in the apparatus, though no doubt some of them were unnecessarily complicated, as to defects in their installation and in their methods of use.

In the first place, the pipe connections between the automatic gas-testing apparatus and the boiler flues were made too long and had too many joints, with the result that air leakage occurred and in some cases the pipes corroded up. Another common cause of failure was the blocking of the filter used to remove the soot and moisture from the gases before they were tested; but the most general cause of failure was the placing of the apparatus in charge of an engineer or stoker who had had no previous training or experience in the care of delicate mechanism or glass apparatus.

The Causes of Trouble

To deal with these causes of trouble in order, the connecting pipe from the recorder to the individual boiler flues should never exceed 30 ft. in length and should be constructed, not of iron or lead, but of 6-ft. lengths of glass tubing, ½ inch in external diameter, joined to-

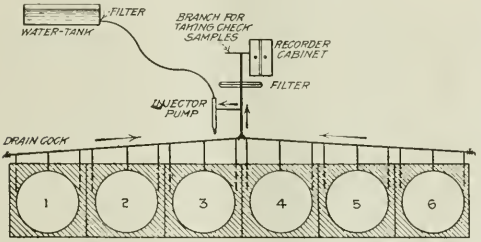

FIG. 3. DIAGRAM OF GAS CONNECTIONS FOR A BATTERY OF SIX LANCASHIRE BOILERS

gether with couplings of the best red rubber, wired on. An engineer would, of course, specify metal tubing with screwed joints for this purpose[1], but as a chemist with some practical knowledge of the subject of gas sampling and testing under works conditions, the writer believes firmly in the advantages offered by glass over metal. In the first place it is non-corrodible and in the second place one can see when cleaning out is required, whereas with metal tubes one is absolutely in the dark as to the state of the interior. Gas-testing apparatus ought, therefore, always so far as possible to be constructed of glass, for the two advantages of non-corrodibility and transparency far outweigh all the disadvantages attached to the use of a fragile material, and with care, glass apparatus and tubing can be used for years without renewals of any kind, except at the joints. These joints will require attention, but if good rubber be used they will last six months or more, though they should be renewed at once when the rubber begins to crack.

Tubes and Stopcocks

At each branch to the boiler, or to the main flue, a glass stopcock and T piece must be inserted in the line, with the longer leg pointing vertically downward. The tube that actually passes into the flue is attached to this leg, and must be of ⅝-in. external diameter hard "potash" glass in order to withstand temperatures up to 800 deg. F. without softening or melting. These dependent tubes, where they pass through the brickwork of the boiler setting, should be protected by flanged iron guard tubes ¾ in. or 1 in. diameter, and should be fixed firmly in these with the aid of cork bungs. The glass stopcocks must be regularly cleaned and greased, and once a week the tightness of the whole system of connecting tubes must be tested by closing all the stopcocks and working the water-jet air pump until a vacuum of 8 in., as registered by a gage connected to the line near the pump, is attained. Should this be impossible, the leakage that destroys the vacuum must be sought for and stopped. At frequent intervals the dependent tubes that pass into the flues, also the main length of connecting tube, must be freed from internal soot and dust by the aid of low-pressure steam or by flushing with warm water, the hard glass tubes being withdrawn from the flues and cooled before this treatment is carried out.

One Recorder to Six Boilers

It is advisable to have a recorder installed for every six boilers and to be able to connect this as desired to the flue from either the right or left hand boiler fire (in the case of Lancashire boilers) and to the main flue behind each boiler. (See Fig. 3.) This gives a maximum of eighteen connections on any one line. The cabin or cupboard in which the apparatus is installed should be placed centrally, so that three of the boilers are on one side of it and three on the other. The tubes should be laid with a fall away from the central connection to the recorder, in order that the moisture that condenses in the line may be removed at frequent intervals of time by opening the end stopcock of each branch.

Design of Soot Filter and Water-Jet Pump

The soot filter may be constructed of sheet lead (although a glass one constructed on the laboratory "desiccator" principle would be better) and should be placed close to the recorder, so that there is only one filter on each connecting line, and this can then be kept under constant observation. It must be of the circular flat shallow type, which gives a large filtration area with a small cubical capacity, in order that there may be less "lag" in the test records. The joint between the two halves of the filter is made with a rubber gasket-ring and two external rings of hard lead or iron, provided with bolts and thumbscrews. Glass-wool or asbestos-felt supported on wire gauze is used as the filtering medium; this must be removed and renewed daily or oftener, according to the amount of soot contained in the waste gases. The advantage of placing the filter close to the recorder is that only the gas actually tested is passed through it, whereas if it be placed upon the main connecting line all the gas withdrawn by the pump from the flues will pass through it and it will require cleaning much more frequently.

When an ejector type of water pump is used to abstract the gas from the flues it is advisable to provide a separate water supply tank, fitted with a filtering attachment to retain fine particles of grit and other matter which might stop up the jet of the air pump and cause it to cease working. A steady pressure or head of water is also required in order to obtain satisfactory operation with this type of pump; this is most

[1]See "Sampling and Analyzing Flue Gases," by H. Kreisinger and F. K. Ovitz, Bureau of Mines Bull. 97 (1915).

easily arranged for by installing a separate supply cistern with a floating ball-tap and lead run-off pipe.

Automatic and continuous CO_2 recording apparatus falls into two broad classes, according as the percentage of carbon dioxide gas is measured by direct absorption in caustic potash or some physical characteristic of the gas that is a criterion of the CO_2 contents is observed and measured. In the article following, descriptions and illustrations of all the well-known types will be given. In closing this introductory article, however, it is well to emphasize the great importance of regular and systematic chemical examination of the waste gases in boiler plants, and to urge that the care of any automatic testing instruments installed should be placed in the hands of specially trained men, and not left to the charge of ordinary stokers or shift-engineers who may happen to have a few spare minutes available or may volunteer for the job. Many past failures with such instruments in the boiler house are undoubtedly attributable to the neglect of this latter precaution, and some engineers have made the same mistake with these machines that they made at first with mechanical stokers, and have imagined that as they were automatic in action they did not require skilled attention. The lesson of experience, however, is that automatic apparatus of all kinds demands a well-trained and highly intelligent man to look after it and to keep it in order; and that the most certain way of asking for trouble in the boiler house is to place insufficiently trained men in charge of mechanical stokers and carbon dioxide recording apparatus. When this lesson has been thoroughly learned by chief engineers, the automatic types of CO_2 apparatus will once more come into favor, for with intelligent and skilled attention they can be of the greatest service in maintaining the conditions requisite for high efficiency in the combustion of coal under steam boilers.

Electric Pig Iron After the War

By Robert Turnbull*

At THE meeting of this society held in Pittsburgh in October of last year I read a short paper on the manufacture of low-phosphorus pig iron from scrap shell turnings in the electric furnace. At the time that paper was read this industry was only in its infancy, the total output in Canada being only about 900 tons per month. Today Canada's output is more than 2500 tons, and by the latter part of November the production will be between 4000 and 4500 tons per month. Furnaces are operating at Orillia, Ont.; St. Catherines, Ont.; Collingwood, Ont.; Belleville, Ont.; Hull, Que., and Shawinigan Falls, Que., the two largest producers being St. Catherines and Orillia, where the output per furnace is about 700 tons per month. Furnaces are building in Lakefield, Ont.; Shawinigan Falls, Que., and Vancouver, B. C., the iron produced in all these furnaces to be used for Canadian consumption with the exception of the production of the Vancouver plant, a portion of which will be exported. Canada at the present time is almost entirely dependent on its supply of low-phosphorus iron from electric furnaces, its usual supply of blast-furnace iron from the United States being shut off.

A number of improvements have taken place in tbe manufacture of this iron since I read my former paper. The consumption of electrode has been reduced, some months showing 21 lb. to the gross ton of iron. Kilowatt-hours also have been reduced, the average practice showing slightly more than 500 to the gross ton. Ferro-silicon has been replaced by another product, which reduces the cost and helps the carbon addition. The carbon in the iron is seldom below 3 per cent, and in quite a number of heats 3½ per cent is attained. The cost of producing the iron has gone up, mainly owing to higher labor cost and a general increase on all raw materials, including shell scrap; these items, with the exception of scrap, having increased more than 50 per cent since the Fall of last year.

The following table of 25 consecutive heats shows very clearly the quality of iron being produced today, also the great improvement in the carbon contents:

[1]Silicon desired, 1.00 to 1.25 per cent.

Having been asked by the president of this society to give my views on what will be the probable use of furnaces at present engaged in the production of low-phosphorus iron in after the war problems, I will endeavor to do so, although I consider any statements made at present will be in themselves problematic, as they will depend entirely on the state of trade after the war, which at the present time no one can foresee.

Quality Near That of Blast-Furnace Iron

First of all, the class of iron produced in these furnaces today has not been considered by the consumer to be equal to the grade of iron formerly received from blast furnaces, and, if this is correct, the tendency of the consumer would be to return to blast-furnace iron when he can obtain it. My answer to this is, that the iron produced today in the electric furnace is now so close in quality to blast-furnace iron—it now being possible to attain from 3 per cent to 3½ per cent carbon in this iron—that by the time the consumer will again be able to import iron from the United States he will have become so accustomed to using electric-furnace iron that the deciding factor will be the question of price.

The next question is: Will specifications on steel

*Paper read at the thirty-fourth general meeting of the American Electrochemical Society in Atlantic City, N. J., Oct. 1, 1918. This paper was read prior to the signing of the armistice. The production figures are, therefore, probably erroneous at this time, but the technique and economics of the process are still pertinent.—Editor.

produced after the war, which at the present time allow very high limits for phosphorus and sulphur, be reduced to their former strict limits, which were 0.04 for both phosphorus and sulphur? This issue will have an important bearing on the manufacture of iron in the electric furnace, as should these limits be reduced to their former level, it will be impossible for the steel manufacturer to use the bessemer grade of iron, which he mixes with the low-phosphorus pig, to such an extent as he is doing today, and he will be obliged to use a very much larger quantity of low-phosphorus pig—possibly 100 per cent more. As it is not likely this extra tonnage can be obtained for years to come from the United States, the only source of supply would be the present electric-furnace product. Should, on the contrary, the present high limits be retained the question of price between the two classes of iron would be the determining factor to the consumer, provided the States will be in a position to supply Canada with its requirements in this grade of iron.

Question of Supply Considered

The next question, and what may be considered the most important one, is: Where will the electric furnaces obtain their supply of low-phosphorus scrap turnings when the present source no longer exists? This brings up another question which will be quite a determining factor in solving the problem, and that is: Will the open hearth continue the use of turnings in the charge, as is being done at present?

I think we are safe in considering that the open hearth will discontinue the use of turnings as soon as it can obtain its supply in heavy melting scrap, as the use of turnings in this furnace involves a greater use of pig iron, and there is a much higher melting loss when turnings are used as compared with heavy melting scrap. This loss is not taken into consideration so much at present, owing to the high prices obtained for the finished product and the impossibility of getting enough heavy melting scrap, but more attention will be paid to this when normal competition again sets in.

Before the war a considerable tonnage of steel turnings was available, and as the production of steel in Canada is now at least 100 per cent more than before the war, we may consider that a very much larger quantity will be produced after the war. Eliminating the open hearth as a consumer, this scrap will become, so to speak, a drug on the market, as it was formerly, and the electric furnace, as a low-phosphorus iron producer, will be the natural customer for this scrap. By paying a small bonus on low-phosphorus turnings, machine shops would no doubt be willing to grade their scrap, as they are doing at present with shell turnings, and this would be a complete answer to our question, provided such conditions could be realized.

We must, however, consider the possibility of an insufficient supply of such turnings and what we would expect to do in such a condition. This would bring us back to the old question of smelting ore in the electric furnace, as this would be the only other source of supply left, if the present furnaces were to be used for the production of low-phosphorus iron. Former experiments have shown that iron ore and steel turnings, mixed in certain proportions, give a production very favorable in proportion to the amount of power used, and smelting operations are very easy to handle. The furnace which would be used to smelt such a mixture would be of the continuous type, with a load factor approaching 100 per cent, and, as electric steel furnaces have a very low load factor—in some cases not over 50 per cent—the amount of extra power necessary to produce the same quantity of iron from a mixture of ore and steel turnings, as compared with our present type of furnace melting scrap alone, would not be considerable.

About 1400 kw.-hrs. are required to produce one gross ton of iron from a mixture of 50 per cent metallic in turnings and 50 per cent iron ore, so that our present furnaces, which are of 1200 kw. capacity, could produce 20 tons per day of iron, as compared with from 25 to 30 tons using steel turnings alone. I am not prepared to say how the cost of the iron would compare in the case of the mixture as compared with steel turnings alone, but as no ferrosilicon or fluorspar would be required, and the return in metallic contents charged would be 100 per cent as against 90 per cent with turnings alone, besides a great saving in furnace repairs, this would probably more than compensate for the extra power, electrodes and carbon necessary for the reduction of the ore.

A mixture of this kind permits the use of iron-ore concentrates, the charge being kept porous enough, owing to the presence of the turnings, and as these concentrates can be obtained very low in phosphorus, they could be used to advantage in the production of low-phosphorus iron and permit the use of turnings with higher phosphorus contents. As the operation would be conducted in a reducing atmosphere, the resulting carbon in the iron would be perfectly comparable to the blast-furnace product.

Another use to which the present furnaces could be put would be the melting of iron for foundry purposes. The war having eliminated the exportation of English iron and also iron from the United States, foundries have faced the necessity of confining themselves entirely to Canadian iron, mixed with a very high percentage of scrap cast iron, and, it must be confessed, with good success. As most of the plants which are producing low-phosphorus iron would be suitable for foundry purposes, and as the grade of iron can be controlled very closely and silicon added at little cost, there should be an excellent opening for these furnaces in replacing the cupola for melting purposes, and using nothing but the cheapest cast-iron scrap, including borings, etc., and the metal used direct from furnace to molds, without the use of any pig iron whatever.

A New Bronze-Alloy in Norway

A captain in the Norwegian Navy has invented a new bronze-alloy, the so-called M. bronze, which is particularly adapted for bearings, armaments and machinery parts where a comparatively high hardness is required, and for welding and rolling, according to the weekly bulletin of the Canadian Department of Trade and Commerce. In order to satisfy different requirements the bronze is worked out in three qualities, hard, medium hard, and soft. For use where an especially good quality is demanded and for ships' use there can also be produced a finer quality, like mangan bronze.

Pittsburgh Meeting of the American Ceramic Society

New and Important Data Presented on Graphite, Bonding Clays, Porcelain and Optical Glass—Comparative Properties of Foreign and Domestic Graphites — Tests Under Foundry Practice—Microscopic Studies of Porcelain—Gases Dissolved in Optical Glass

THE subjects covered by the term "ceramics" seem to include about everything from bricks to bric-à-brac; but the crowd that is back of the subjects is one to be respected. The Pittsburgh meeting of the American Ceramic Society was the twenty-first annual assembly; and President Homer F. Staley in his official address, in opening the program, noted that this meeting was of significance in that it represented the twentieth birthday of the society. He then went on to note some of the past work of the society, as well as some of the desirable policies for the future. Among some of the changes he recommended for consideration:

1. The enlargement of the publication activities of the society, in some increased work of the *Journal* of the American Ceramic Society.

2. The employment of a full-time secretary who should also give his full attention to the editorship of the *Journal* and business management of the society.

3. The selection and establishment of permanent headquarters for the society, in some one of the leading cities of large commercial activity and opportunity in the country.

4. The enlargement of the voting membership of the society, and the possible merging of the "associate" membership with the "active" membership.

5. The consideration of the status of the cement and mortar industries, in closer relations with the work of the society.

The report of the secretary, Professor Charles F. Binns of Alfred University, who is perhaps the dean of American ceramics, showed the satisfactory financial condition of the society, and recommended the appointment of standing committees on the following subjects, which roughly would seem to include the more important branches of ceramics:

1. Glass. 2. Enamel. 3. Pottery and porcelain. 4. Refractories. 5. Brick and tile. 6. Terra cotta and faience. 7. Abrasives.

The formal reading of papers disclosed a large and varied list, some 52 papers being titled for delivery. Most of these were of a high order, both in the selection of topic and in the method of treatment; and it is worthy of note that nearly all of these showed that the contributors were well equipped with the latest theory and technique in their respective lines.

Among some of the more highly emphasized subjects were those of graphite, enamel, optical glass, and porcelain. The subject of graphite occupied most of the program of the first afternoon.

Symposium on Graphite and Bonding Clays

Mr. M. C. Booze of the U. S. Bureau of Mines at Columbus, Ohio, led in a series of seven papers from that fountain of ceramic activity. Mr. Booze showed the comparative properties of several bonding clays, in a curve which was made up of the summation and averaging of specific individual properties, such as strength, quenching action, resistance to oxidation, shrinkage, etc. The results are striking, though there seemed to be some doubt as to the reliability of the method of averaging, as compared with desirable practical results, but the paper was only part of the symposium offered by the able set of workers from the Columbus U. S. Bureau of Mines.

Interwoven with this set of papers was one by Professor G. H. Brown (and Mr. E. C. Hill) of Rutgers College, "Properties of Some Bonding Clays and Their Mixtures With Graphite." Professor Brown's paper was quite elaborate, being illustrated with several curves which showed the relations of the plasticity, refractories, vitrification, shrinkage, porosity, etc., at low and higher temperatures of treatment. No attempt will be made to reproduce this very scholarly article, but it may be said that Professor Brown determined the physical properties of a number of typical "bonding clays," for mixing with graphite, when burned under oxidizing and reducing conditions. In addition to typical crucible clays now in use, he also examined a few so-called "low-grade" clays which hitherto have not been regarded as suitable for crucible manufacture. As a result, Professor Brown concluded that the crucible manufacturers have been restricting themselves to an unnecessarily limited field. Some materials which have been hitherto rejected have given surprisingly good service in graphite crucibles of standard size and when used under commercial conditions.

Comparative Foundry Tests on Domestic and Foreign Graphites

As one paper followed another, most of them on graphite, it became evident that there was a sequence; and this became especially focused in interest in the paper of Dr. Reinhardt Thiessen, on "The Effect of the Shape of Graphite Flakes on the Structure and Durability of Crucibles," and that of Mr. R. T. Stull, on "Tests Under Brass Foundry Practice of Crucibles Containing Ceylon, Canadian and Alabama Graphite." In a word, both of these papers were aimed directly at the main question of comparing American with the best foreign graphite, which has been regarded, till recently, as that from Ceylon.

Dr. Thiessen is an expert with the miscroscope and the ultra-microscope; and those who had heard some of his earlier papers on related subjects, such as the structure of coal, were prepared to get at something definite, and were not disappointed. Dr. Thiessen showed that the prevailing structure of most American graphites was of rather large and rather rounded grains; and that most of these had such a distinct

lamination that the resulting mixture was sure to be laminated and to show the weakness of laminated cleaving. But the Ceylon graphite was shown to be made up, for the most part, of large and small grains, and with much irregularity of outline, but largely of angular shapes; and the cleavage was not of the always parallel lamination, but of much irregularity in dimension and direction, so that, when mixed in crucibles, the whole would develop a much more coherent mass than was possible with the average American graphite. Moreover, Dr. Thiessen showed that the chemical reaction of most graphites is "acid," which, with the "negative" reaction of most bonding clays, was sure to throw down a precipitate, which would only work disastrously in the desired bonding effect. So he induced "peptization" as a remedy, and with beneficial results; as shown by incidental reference to the ultramicroscopic examination of the well-burnt crucibles.

Mr. Stull's paper, on foundry practice of crucibles with Ceylon and American graphites, followed up this clear impression of some distinct progress in the mastery of the difficulties of finding a substitute for Ceylon graphite. This paper was all the more gratifying because it threw much light on the recent newspaper reports that the American manufacturer had been able to substitute for a considerable amount of Ceylon graphite the home product in the making of crucibles.

These tests were so conducted that they would well simulate the conditions of actual practice. The number of heats was noted, and this runs from ten to thirty or thirty-four, depending on the composition of the crucible, the conditions of manufacture and the kind of use the crucible might receive at the hands of the workman in the factory. Moreover, the crucibles were subjected to the action of two kinds of brass, one which melted easily and had a "mild" action on the crucible, and another that exerted a rough and heroic action on the crucible, both in the manner of melt and in the temperature of melt. Mr. Stull's paper was accompanied by several remarkable groups of curves, which showed many of the conditions of composition and treatment, running all the way from 100 per cent Ceylon and no American to no Ceylon and 100 per cent American graphite.

The best type of American graphite was found in the Alabama variety, but this Alabama graphite is mainly of a "flaky" texture and so, to change the flakes to grains, recourse was had to coking it in briquets, compressed under high pressure with tar as a binder. The anticipation was that the grains thus produced would act better than the original flakes of this Alabama graphite, but just the contrary was found to be the case. Incidentally, one of the seven papers from the Columbus workers was devoted to the effects of this variable pressure and tar content in briqueting the Alabama graphite.

Good Results From Alabama Graphite

In the main paper, by Mr. Stull, it was shown that, while some of the lowest and some of the highest number of heats possible for the crucibles were found for the straight Ceylon graphite, yet the careful tracing out of the curves of the mixtures of the Ceylon with the Alabama flake and the Alabama grain (coked) and with the "mild" and with the "hard" brass showed that some of the best maxima of possible heats were obtained with mixtures of the Alabama flake, and with increasing proportions of the latter. To be sure, these results are only tentative, and were advanced as showing the possibilities, but as such they are distinctly encouraging.

It must also be said that the conditions of working were arduous and exacting in the extreme. It takes nearly a month's waiting to manufacture a graphite crucible of the size used—about No. 60—and after that, when the crucible gets to the foundry, it ought to have three or four weeks more to dry out thoroughly; and doubtless many of the crucibles tested were not sufficiently aged and dried out to rightly undergo the best strains of practical efficiency. There were also many incidental points of interest; as the correspondence between wholly different curves, as the rising and falling at the percentage composition points of about 23 per cent, about 45 per cent and about 68 per cent of American (Alabama) flake—rising at 100 per cent in one case to over 28 heats per crucible. Moreover, the tests were conducted in sets of ten crucibles, and the correspondence of heats endured in the same set was very good.

Following the group of papers on graphite, there were the distinct sets of papers on enamels, on porcelain and on glass and optical glass.

Simple Chemical Tests for Enamels

In the enamel group should be noted the very practical paper by Mr. E. P. Poste of Elyria, Ohio, who described his search for some cheap, readily available and fairly constant acid which might be used by the large group of manufacturers who would not stop to employ expensive chemical tests but who needed some standard for the solvent effect of common solutions on enamel in its common uses. After a careful comparison of such acids as acetic, hydrochloric, nitric and sulphuric, he found in citric and tartaric acids almost the desirable objects of his quest. These acids are solid substances, they can be bought at every drug store, and they are fairly stable and permanent in storage. Thus it is perhaps possible to recommend a simple formula for the use of those interested, by means of which the solvent action of culinary solutions on enameled ware can be easily studied on a common standard. Moreover, citric and tartaric acids represent the common fruit solutions of domestic use to which enameled ware is commonly subjected. The tests were not quite complete with the paper, but the indications are that tartaric acid is perhaps the more desirable, as it can be easily obtained, and a standard solution can be made up, by weight, and with the simple addition of water.

Mr. Poste also described a search for clays by which to control the fusion temperature of enamel, illustrated by a curve of relative differences of increased temperatures of fusion.

Mr. P. D. Landrum of Cleveland described an attempt to make an enamel, using the clouding effects of titanium oxide (rutile) instead of the well-known tin-white substance. He found the presence of iron, which, strange to say, did not seem to control the color, though it may have interfered with it. But while he obtained the opaque effect, he invariably obtained also a yellow-

ish tint, which is not considered desirable in the trade. He noted the inference that the titanium, or some titanium compound, is precipitated in part in the enamel as "invisible" microscopic crystals.

Blistering of Enameled Steel Caused by Entrained Gases

One of the most interesting papers in the enamel field was by Mr. Chester Treischel and Mr. L. E. Barringer, of the General Electric Co. at Schenectady, on "The Cause and Control of Blistering in Sheet Steel Enameling." This paper was prefaced by the exhibition of some remarkable samples of "blistering," some of the specimens showing blisters of several inches in diameter. These were not between the enamel and the steel sheet, but were clearly in the steel body itself, causing the steel to split or laminate itself into still thinner layers. Mr. Treischel noted that metals are known to absorb and to transmit gases with great readiness, and the metals do not give off all of the absorbed gas on simple heating. Moreover, in the process of rolling thin sheet steel, it is a common matter for small bubbles of air to become entrained between the sheets, and these bubbles of air are often rolled out between the sheets, with the metal, attaining to a considerable area. These entrained gases, as hydrogen, or some of the entrained air, may cause serious difficulty. Tests were made to find the conditions of avoiding the absorption of hydrogen in "pickling," and it was found that by the use of a 3 per cent solution of acid the time was not seriously increased, and with careful rubbing off of the scale, before washing, better results were obtained.

Of course, many of the subjects must of necessity overlap; and this was well illustrated by papers on "The Manufacture of Glass Pots" and "The Casting of Porcelain Pots," which naturally were grouped together. As the program approached the manufacture of optical glass, interest was quickened by papers that brought out the nature of the elaborate and refined methods used.

Mr. W. S. Williams and Mr. C. C. Rand gave a paper in which this careful, methodical system was magnificently shown. The successive operations of drying the pots, burning the pots, melting the charges, stirring the melt, cooling the melt, and annealing the melt—each and all of these were shown to be carried on with the most refined control both of temperature and time; so that at any stage of the process the treatment of the pot or of its contents was guarded and foreordained with the utmost nicety and exactness, both in temperature and in time allowed. One interesting detail was a curve of the "stirring circles" followed. Another nice contrivance was the diagram of a "stirring-rod thimble," the use of which was obvious but which shows the nice attention given to the avoiding of contamination in the stirring of optical glass which seems to be an indispensable part of the process to secure uniformity of mixture and the removal of bubbles.

Gases Dissolved in Optical Glass

But perhaps the most startling and suggestive paper on optical glass was one by Professor E. W. Washburn of Urbana, Ill., entitled "Gases Dissolved in Optical Glass." He illustrated the subject by referring to the escape of carbonic acid from common "soda water." With this test as a cue, he described the attack on optical glass. The fundamental experiment was one in which a sample of good glass was melted in an inclosed steel box; then the interior of the box was connected with a vacuum, on which the whole pot of melted glass, finding escape for its contained gas possible from the reduced pressure, foamed up over the top of the pot, and this foamy glass when cooled resembled a light, spongy mass, as one can imagine who did not see the sample passed around. Professor Washburn then described in detail how he followed up the isolation of such occluded gases, and the analysis thereof, certainly determining eight-hundredths of one per cent of oxygen, by weight, and three-hundredths of one per cent of carbonic acid, a total of eleven-hundredths of one per cent by weight of dissolved gases. The mere momentary inspection of Professor Washburn's samples is enough to suggest the nature and complexity of the new problems involved in the production of perfect optical glass.

This was followed by a paper on "The Defects and the Testing of Optical Glass," by Mr. A. R. Payne of the U. S. Bureau of Standards at Pittsburgh. This remarkable paper, which without the accompanying slides is only "'Hamlet' with Hamlet left out," gave a clear catalog of the "seeds, striæ, stones and strains" found in optical glass and which must be avoided. In detail, it may be noted that Mr. Payne noted the "sheet," the "band," the "comet," the "hair" and the "surface" striæ, with some directions as to their causes. It is to be hoped that most of these illustrations may be preserved and published.

Practical Manufacture of Optical Glass

Of course, much of the program was characterized by refined theory and practice, but the charge of undue theoretical treatment of subject was well offset by such a paper in the optical glass list as that by Mr. George W. Morey of the Spencer Lens Co. of Buffalo, who gave the society a most admirable digest of his own actual and practical experience in making optical glass for the U. S. Government. He described in detail, briefly and to the point each of the stages of his method and treatment. One of the charms of this paper was the original and commonsense way in which Mr. Morey analyzed the conditions of initial and partial melting of the charge, with the inevitable results that those conditions must have on the rest of the charge and on the subsequent treatment. Thus, if the charge melts first at the top, then the part melted first flows down through the rest of the unmelted charge, leaving the top of the charge deficient in fluxing power. Moreover, this top part of the charge is the part through which the later escape of the gases given off must take place. Follow up this simple mental picture, and Mr. Morey's method of cutting out the hand stirring and introducing the mechanical stirring at each of the introductions of the parts of the full charge, and it is easy to see why he attained a complete cycle of treatment in a regular run of two days, and with most excellent results.

The subject of porcelain received much attention in quite a number of interesting papers, both from the theoretical and the practical standpoint.

It seems to be the gradually growing consensus among the experts who have given the matter careful consideration that the body of well-baked porcelain, and that having the most perfection of strength, translucency and resistance to solvent chemicals, is characterized by the generous production of a matte of interwoven crystals of sillimanite. Now, sillimanite is a well-known mineral, which occurs in certain gneisses, granites and similar rocks; the chemical composition of sillimanite is given as Al_2SiO_5; and the mineral is connected with its petrographic brethren, andalusite and kyanite, in that they all have the same empirical composition. The study of thin sections of porcelain mixtures shows that sillimanite is gradually produced as the quartz is absorbed by the matrix of the melt, and the approximation to the perfect porcelain composition and texture is paralleled by the attendant growth of the needles of sillimanite. All this was repeatedly shown by such good papers as that by Mr. A. B. Peck of the U. S. Bureau of Standards at Pittsburgh and of Mr. A. S. Watts of Columbus, Ohio; and some of the same methods of examination were employed by Messrs. J. W. Wright and S. I. Sewell of the U. S. Bureau of Standards at Pittsburgh, in their paper on "Some Physical Properties of Commercial Porcelain Bodies."

A typical mixture for making porcelain may be taken as 15 to 20 per cent of quartz, 30 per cent of feldspar, and the balance of ball clay and china clay in about equal proportions, say 25 per cent of each. Now, Mr. F. H. Riddle, in his paper, "Further Studies in Porcelain," showed that the development of the desirable structure and properties of good porcelain seemed to be largely dependent on the length of time used in grinding, not half an hour to an hour, as is the usual custom in commercial practice, but two or three hours. Further, Mr. Riddle showed that this extra grinding seemed to produce better results than quenching, and the extra time given to grinding seemed to be more important than the percentage of feldspar added to the original mixture. He also noted the remarkable influence of small quantities of oxides of calcium and magnesium in shortening the time of "maturing" the melt, and at a somewhat lower temperature.

The special question of casting pots for melting porcelain mixtures was considered in a well-illustrated paper by Messrs. J. W. Wright and D. H. Fuller of the U. S. Bureau of Standards at Pittsburgh.

The incidental use of the holder or jar for ball-mills was considered by Mr. C. W. Parmelee of Urbana, Ill., in a most interesting paper on "Porcelain Bodies for Ball-Mills," in which he examined in detail the various mills and machines for getting at the main idea of what is done and what is meant by the work and effect of "impact" and "rattler" in the tests. Comparative results were given for the action on quartz, clay and feldspar and the subject will be pushed to ascertain the best material for the ball-mill container.

Defects in Pyrometer Protection Tubes

One interesting phase of the actual necessities of present practice and of not finding material that ought to be at hand, but is not, was brought out in the paper by Mr. F. A. Harvey, of the Semet-Solvay Co. at Syracuse, N. Y., on "Porcelain Pyrometer Protection Tubes." This paper disclosed a most distressing state of things. Mr. Harvey is manager of a practical commercial laboratory, and while there are optical pyrometers that can give the thermal conditions for almost any temperature, yet it is indispensable for his work that he should have a graphic record to trace the stages of work. He had a pyrometer protection tube of some unknown make of fireclay that worked beautifully, but on its accidental breaking from the carelessness of a workman, he was unable to find a satisfactory substitute. Among all the attempts he made he found nothing completely satisfactory for the high temperatures involved—some 1450 to 1500 deg. C.—but the most approximate material was found in a "S. C. P." tube from Japan. The suggestion was made in the discussion that there are or ought to be registering optical pyrometers that would serve the purpose; but that does not seem to be quite worked out for the conditions required in Mr. Harvey's work. The paper is only another evidence of the quick response of American technique to the live needs of the times.

Cause of Dielectric Failure of Porcelains

Probably one of the most dramatic features of the porcelain papers was brought out in those bearing on the existence of quartz in porcelain, and its undesirability. This question was brought out, without evasion or camouflage, by Mr. A. S. Watts of Columbus, Ohio, in his paper, "An American Porcelain Containing No Free Quartz," and further sharpened by the "Suggested Discussion" on "A Possible Cause for the Dielectric Failure of Porcelains Which Are Apparently Free From Mechanical Defects," by Mr. Chester Treischel of the General Electric Co., supported by Mr. L. E. Barringer of the same company. In a word, the theory was put forward by Mr. Treischel that quartz is affected by the high potential strains of the alternating current. It is well known that when quartz crystals are subjected to high potential charges, at opposite axial points, they also become subject to distortion in dimensions and figure, and these may result in strain and fracture. This is the well-known "piezo-electric" phenomenon (pressure, electric strain). This may explain the failure of porcelains otherwise well fitted to endure the high potentials of insulators. Mr. Treischel, with most naive witticism, frankly confessed the danger of speculation, as he enumerated the three uses of a theory:

1. To explain facts as they are.
2. To develop further facts.
3. To give intellectual satisfaction.

Mr. Barringer read several letters from various noted specialists, giving more or less admission to the new theory, but he was frankly looking for light; and when such men, from such companies, frankly avow their sense of need for further light, it betokens some possibility of unlooked-for progress. Mr. Barringer noted that there are a dozen oxides that might be used as substitutes for quartz in porcelain, but this may be regarded as only the beginning of a new and marvelous chapter on the composition and manufacture of high-grade insulating porcelain.

In addition to the formal program, there was the usual banquet, presided over by Professor C. F. Binur.

ANNUAL BANQUET AT ASTOR, FEB. 4, 1919

Seated at the speakers' table are (from right to left): E. R. Behrend, J. Newell Stephenson, Dr. Charles P. Steinmetz, Thomas J. Keenan, Secretary T. A. P. P. I.; George W. Sisson, President A. P. P. A.; Justus A. B. Cowles, G. H. Mead, H. P. Carruth, President T. A. P. P. I.; Judge Charles F. Moore, Toastmaster; Robert W. Wolf, Henry E. Fletcher, Stuart D. Lansing, Dr. H. P. Baker, W. F. Robertson, Raymond S. Hatch.

Paper Associations Hold Joint Convention

Annual Meeting of the American Paper and Pulp Association and the Technical Association of the Pulp and Paper Industry—Economic and Technical Questions Discussed—Vocational Education Campaign in the Pulp and Paper Industry to Be Prosecuted

THE Technical Association of the Pulp and Paper Industry held its fourth annual convention in New York Feb. 3 to 6, conjointly with that of the American Paper and Pulp Association, in which body it was elected an organization member. It was decided that the scope of the A. P. P. A. should be extended to include the paper product manufacturers such as fine stationery, writing tablets, fiber containers, envelopes, merchandise bags, wall paper, etc., in addition to the present member organizations, who are strictly engaged in the manufacture of primary products such as binder board, cardboard, cover paper, glazed and fancy paper, gummed paper, tissue paper, vegetable parchment, waxed paper, wrapping paper and pulp.

The TAPPI program of forty addresses and committee reports was very inviting and brought forth about two hundred members from all parts of the lands of the eagle and maple leaf. Dr. C. P. Steinmetz of the General Electric Co. was the guest of distinction and proved his versatility by delivering an address on "The Principles of Waste and By-products." The keynote of his address was that chemistry is the greatest of the sciences, that the coal-tar industry is an example of man learning to control and utilize all the products given to him by nature and that the pulp and paper industry should make every endeavor to find uses for its marvelous wastes and turn them into by-products.

As the addresses, discussions and reports will be printed in full in the current issue of *Paper*, no attempt will be made to review the meeting in sequence but brief notes will be made to witness that the paper industry gave evidence of broad industrial scientific activity. In connection with Chairman Martin L. Griffin's report on the black ash furnace alkali stack losses, the Cottrell electric precipitation process was thoroughly discussed. The Brown Company has taken the initiative and installed the process in its Canadian sulphate plant, where it will receive capable development and perhaps lead to broad application in the alkali pulp industry. Mr. J. A. DeCew described his flotation process as entirely successful in recovering the pulp and china clay from the waste liquor from the Fourdrinier screens by simple air foaming and floating off the concentrated solids with a yield as high as 80 per cent. Not much good news was forthcoming about sulphite liquor, a small amount of highly refined concentrate being reported as in use as leather filler, and the raw concentrate as core compound and road binder, but the exhaust lines to the river still are carrying their polluting charge in undiminished volume.

The Morterud Process

The Morterud forced circulation external heater process of cooking pulp was described by O. L. Berger. The advantages to be gained by the successful operation of this process are revolutionary, but it is found that in American installation to date troubles have been experienced in getting tubes for the heater that will stand up against the corrosion of the circulating liquor. The process is reported by Mr. Berger to be working very successfully in Norway and full knowledge of the materials of construction used there are expected to make equally successful operation possible here. As the war has made it difficult to set stringent specifications and get delivery, it is hoped that the enterprising manufacturers who have taken chances and invested in this

new type of equipment will be able to obtain satisfactory tubes. If the Morterud process proves to be materially practical, much less digester liquor will have to be used and real progress will be made in reducing the volume of this waste to economical concentration.

"Common Sources of Error in Sulphite Liquor Testing," by W. E. Byron Baker, was a thorough discussion of analytical work, but would have served to better purpose if printed copies had previously been sent to the mill chemists so that time for real consideration of the author's new method could have been available and discussion held at the meeting. Great interest was not excited, as all but a few members adjourned to the halls.

Selecting Suitable Employees

The popular talk on vocational analysis for selecting suitable employees, by Dr. Katharine M. H. Blackford, was keenly listened to and made so favorable an impression that the time was extended another hour to allow the little wizardess to tell all about the vocations that the outer appearances of Messrs. Wolf and Fletcher indicated, and true to her reputation as an employment manager, she filled them out a card for the very jobs at which they are recognized by all the members of the association as eminently successful.

Dr. T. Poole Maynard spoke concerning the American clays and requested that the paper manufacturers cooperate with the kaolin producers in adapting our great domestic resources to this field. Dr. Maynard believes that some of the infinite variety of the American china clays are suitable and that the greater the co-operation the sooner will the problem be solved. Points brought up were that the pulverized and air floated clay contained much abrasive grit which cut the wire cloths seriously. Alkaline earths were also mentioned as undesirables, forming mineral soaps with the resins and perhaps giving rise to the so-called "tiny sheet." As most secondary clays were deposited in the presence of marine life, small amounts of lime are usually present, even when the reef formations are not found in immediate connection. No doubt the ground water of the entire territory below the crystalline line contains lime salts. However, there are some primary clays in Northern Georgia and Alabama which have been passed up by the investigators that are free from even traces of alkaline earth bases and with proper aging and preparation will resemble the imported material more closely.

Several of the groundwood mills are reported as having trouble with rusting pulp. One plant recently burned five hundred tons for fuel. When the rusts are examined under the microscope, a small black worm is found. Mr. John Stadler reported that his plant had had a touch of it several years ago and that it had been found that if the pulp was sterilized with chlorine, no rust worms would develop during storage.

Vocational Education Fostered

The greatest activity of the association is probably its endeavor to foster vocational education in the pulp and paper industry. It is now about to get a treatise out by contributions of a large staff of specialists on the following: Wood preparation, sawing into blocks, conveyors, piling, measuring, barking, drum and knife barkers, hand cleaning, splitting, chipping, screening, rechipping, drying, conveying to drip bins, hazards, mechanical pulp, kinds of woods, conveying blocks, types of grinders, Hall process, operation of grinders, dilution of pulp, losses, power, hazards; treatment of pulp, sulphite pulp, soda pulp, sulphate pulp, bleaching pulp, analysis and testing of pulp and raw materials, analysis of allied paper materials, preparation of rag and other fibers, esparto, waste papers, beating and mixing, loading, sizing, coloring, paper making, the paper machine, tub sized papers, finishing operations, special Fourdrinier machines, cylinder machine, special papers and boards, paper testing, trade customs, general mill equipment, laboratory equipment, glossary of terms. The association expects to spend $30,000 in preparing the manuscript, which will be turned over to a publishing concern for printing. This is the first time any large industry has followed such a program and no doubt the benefits to be derived will be as great as anticipated. Several other branches of industry will do well to follow this excellent example.

New Work in Wood Chemicals

Researches by the chemists of the Forest Products Laboratory at Madison, Wisconsin, upon the production of ethyl or grain alcohol from wood waste which before the war made possible a materially increased output were continued as a means of conserving foodstuffs and of relieving tonnage for overseas transport. Similar researches to produce the same product from waste sulphite liquor in pulp making have shown and demonstrated commercially that the yield of ethyl alcohol from this source can be increased more than 50 per cent.

Field studies were made and aid was given during the war to several large hardwood distillation plants upon the matter of temperature control as a means of increasing output. By use of proper method the increased output amounts to 3 gal. of 82 per cent spirit per cord and the acetate of lime product was increased as much as 5 lb. per cord of wood distilled. In addition to this, large quantities of fuel were conserved, due to the more efficient temperature regulations. This work supplemented much more extensive efforts conducted before the war.

Extensive researches were carried out upon the preparation of acetic acid by the fusion of sawdust with sodium hydroxide. It was shown that 15 to 20 per cent of the dry weight of the wood can thus be converted into acetic acid. This work is at present awaiting commercial or large-scale application.

Novel Use for Carbon Dioxide

Carbon dioxide has been successfully used in Australia for exterminating the weevil which has been destroying stored wheat in vast quantities. The infected wheat is stored in air tight stackhouses into which carbon dioxide is pumped until the live weevils are destroyed. The eggs and grubs which remain are killed by heating the wheat in special machines to 140 deg. F. for three minutes. It is claimed that the character of the wheat is unaffected and that there is no tendency for weevils to develop again unless exposed to a fresh source of infection.

American Sulphur Industry Expanding

Brief Account of the Sulphur-Bearing Saline Domes of the Gulf Coast—Operations at Matagorda, Enormous Boiler Equipment, Water Superheaters and Pumps—Fuel Cost of Primary Importance Because of Low Heating Efficiency

DUE to the patents granted to the late Herman Frasch during the period from 1891 to 1903, the sulphur industry has grown up in the United States under a patent monopoly. The development of the Louisiana deposit has long been recognized as a noted achievement, though it was as recently as 1912, when the Perkin Medal[1] was awarded to Mr. Frasch, that scientific literature began to bear any appreciable American sulphur content. How extensive the formations and what the origin of these great subterranean masses of sulphur were has never ceased to excite the keenest attention. Those who have studied the formations of the southern sections of the Gulf States, Georgia and all of Florida do not require elaborate geological theory to understand that this area is entirely of sedimentary origin, with the northern outcrops of the inclined strata indicating a thickness at the present coast of about 12,000 ft. This two-mile depth of fill may be said to consist entirely of the decomposition products of the original continental rock formation interspersed with marine animal remains. During the varying life and climatic periods, many individual strata were formed. It is of interest to note that great dislocations have taken place in these strata, especially near the present coast line, with resulting vertical seams offering free channels for the upward and downward passage of ground water. Whether the tidal forces due to the shifting waters of the Gulf or strains set up by temperature changes, etc., brought about these faults is open to conjecture. That similar eruptions are taking place in this locality during the present period is evidenced by such catastrophes as the Galveston tidal wave in 1900. The gulf being shallow, major subterranean eruptions in its floor are followed by high seas.

[1] Metallurgical and Chemical Engineering, Vol. X, pp. 73-82.

At certain points along these faults the so-called dome phenomena take place. As is well known, rock salt and large bodies of either petroleum or sulphur occur in them, the origin of which may be due to the brine being concentrated to saturation in the hot zone at the base of the fault, the destructive distillation of the marine fossils and the reduction of the sulphates by the hydrocarbon in some instances with the ultimate result that great quantities of sulphur are produced and the available petroleum consumed. There are many of these sulphur deposits in the Gulf Coast region, but commercial mines are at present confined to three localities only. The Union and Freeport Company properties have been long in operation, while the third, located near the mouth of the Colorado River at Matagorda, Texas, is now 90 per cent equipped for operation and will be known as the Texas Gulf Sulphur Co.

The surface indications of the domes are low mounds rising a few feet only above the flat alluvial plain which constitutes the Gulf Coast section. In the case of the Matagorda dome, the elevation above the plain is only some 15 feet with a diameter of approximately 3500 feet. The elevation is so slight that it cannot be distinguished in a photograph, the steepest grade being under 2 per cent. On the surface, the dome consists of alluvial material with no rock outcrop of any kind. Wells were originally located on these domes because of their elevation and small liability to be flooded during storms.

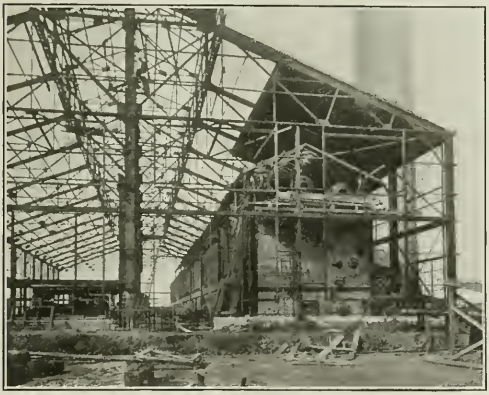
After the discovery of oil at Spindle Top near Beaumont, Texas, many domes were explored for oil, among others that at Matagorda. The mound produced some oil, but the total output was small and it was soon abandoned as an oil field. In the course of drilling for oil, sulphur was identified in the cuttings from several wells. At the time, however, little importance was attached to

the presence of sulphur. At a later date, the existence of important quantities of sulphur was proved, but the dome was not thoroughly explored until the Texas Gulf Sulphur Co. started drilling in the summer of 1917. Extensive drilling has confirmed the early records, and the deposit ranks today as one of the largest and most accessible sulphur reserves in the world.

The company was disposed to postpone the erection of a boiler plant until the end of the war, but the increasing demands of the Government for sulphuric acid and the possibility of a shortage of sulphur-bearing materials made it advisable to begin construction immediately. With the encouragement and priority grants of the Government, the company has erected during the war a modern boiler plant with all accessories and equipment needed for economical operation. The company will probably start production within sixty days at a rate of not less than 1000 tons daily. The reserves of high-grade ore, stated to contain at least several million tons of sulphur, are adequate for many years' production.

Matagorda Dome

The conditions found by drilling show a very flat-topped (practically horizontal) salt dome occurring at a depth of about 1000 ft. below the surface. The salt has not been drilled through, but is presumed to be of great thickness. Overlying this conformably is a stratum of salt and gypsum, while above this is the sulphur. The strata containing the sulphur show alternating layers of calcite and some gypsum. The sulphur horizon has been stated to be in the form of a half-dome, so that while the strata of gypsum and calcite are continuous,



BOILERS, PUMPS, ETC., USED IN HEATING ABOUT FOUR MILLION GALLONS OF WATER TO 325 DEG. F. WITH WHICH THE SULPHUR IS MELTED

a portion of these strata on one side of the dome contain little or no sulphur.

Above the sulphur horizon is a series of sediments consisting mainly of gumbo, shales (with shell), clays and sands. Embedded in the unconsolidated sediments are masses of limestone.

On the sides of the dome, where the dip is steep, drilling shows that the unconsolidated sediments extend to much greater depth, the underlying rock strata not having been reached. There is, then, not a mere flexing of the strata, but a distinct rupture involving immense forces over a comparatively small area. Subsequent erosion of the surface has left only small mounds to indicate the great displacement under the surface. In the nature of the case no correlation of upper strata is possible between various drill holes, nor is the sulphur horizon overlaid by the same formation in all cases. In general, of course, the limestone beds are found to be thicker and more numerous as greater depth is attained. In the case of Matagorda it might be more correct to refer to the dome as a plug practically flat on top with nearly vertical sides.

The manner of occurrence of sulphur in the mounds of the coastal plain region makes prospecting hazardous and expensive. There is no surface evidence except that furnished by the topography, and many of the mounds have been proved to be barren of both oil and sulphur. The physical character of the sulphur horizon has an important bearing upon the success with which the superheated water process may be applied. The formation must be sufficiently open to permit the hot water to circulate rapidly. Its depth and the overlying strata must be such that hydraulic and steam pressures can be maintained. The formation should be free from large subterranean water channels or passages through which the hot water might escape without obtaining sufficient contact with the sulphur. It is stated that the Matagorda deposit fulfills all these conditions to a desirable degree.

Main Features to Be Considered

From a practical standpoint, the main features to be considered in sulphur operations are transportation, fuel and water. As the product mined is cheap, it is apparent that a low transportation cost to the main sources of consumption is required to maintain economical prices. The Matagorda deposit is located on the Santa Fe Railway and being only two miles from Matagorda Bay and seventy-five miles from Galveston, will enjoy cheap ocean freights to the Atlantic seaboard as well as to foreign markets.

Fuel oil is obtainable at low cost either from the Texas oil fields or from Mexico in tank steamers. The company will require a minimum of 2000 barrels of oil daily.

The fuel efficiency of the process adopted in mining the sulphur is very low, generally under 3 per cent, comparing the heat units in the fuel with the heat necessary to melt the sulphur. A great deal depends on underground conditions. In some cases, large water courses are present which dissipate the hot water and reduce the efficiency. None of these openings have been found at Matagorda, however, so a high heat efficiency is expected. The main cost of producing sulphur is in the enormous fuel consumption, and the commercial success of the Frasch process was due to the low cost of fuel oil. It is estimated that from three and one-half to four and one-half million gallons of fresh water will be required daily, and in order to obtain this large supply shallow wells have been sunk and arrangements completed to utilize Colorado River water.

The pumping station occupies a space about 280 ft. long by 100 ft. wide. The equipment consists of fourteen 702-hp. Stirling boilers, oil fired, equipped with soot blowers and designed for 200-lb. steam pressure;

two 500-kw. General Electric steam turbo-generators, non-condensing, 2300 volt, 60 cycle, 3-phase; four Laidlaw steam-driven air compressors, each with displacement capacity of 475 cu.ft. per minute at 500 lb. operating pressure; three Webster feed water heaters, each with capacity to heat 3350 gal. per minute from 90 to 160 deg.; three Epping Carpenter boiler feed pumps 16 x 9 x 18 in. The hydraulic equipment is as follows: One 14-in. Duplex Worthington steam service pump (used as spare); three 6-in. Allis-Chalmers centrifugal service pumps; eighteen 10 x 6 x 16 high pressure mine water pumps; seventeen 12 x 7 x 16 low pressure mine water pumps, both Epping Carpenter manufacture; eight mine water heaters designed to use live steam direct for heating. The normal operation of the water system is as follows:

The service pumps deliver to the feed water heater, thence to the feed pumps and also the low pressure mine pumps, thence through the mine water heater to the high pressure mine pumps, and thence to the sulphur wells. By-passes are arranged so as to make the piping system flexible. Two radial brick stacks 200 ft. high by 13 ft. in diameter built by the M. W. Kellogg Co. complete the power house equipment. A water reservoir of 240 million gallon capacity assures tiding over the Texas drought. A system of shallow wells has been bored as an additional source, should the Colorado River stay dry for any unusually long period.

Oil is received from tank cars, pumped to two steel storage tanks 114 ft. 6 in. in diameter by 30 ft. high. From there it is pumped to two underground concrete storage tanks, each having 1200 bbl. storage capacity, whence three 7½ x 5 x 10 steam pumps deliver the oil direct to the boilers. These tanks and pump house are located about 140 ft. from the pumping station. Two oil heaters for warming oil up to the necessary temperature before combustion are located in the pumping station. All oil tanks and outside oil pipes are provided with steam pipes or coils in order to keep the oil sufficiently warm to flow in cold weather.

Machine Shop and Warehouse

The machine shop is approximately 116 x 75 ft.; the warehouse 170 x 60 ft. The machine shop has one 19-in., one 16-in. and one 12-in. lathes, one 25-in. shaper, one 12-in. pipe threader, one 6-in. and one 2-in. pipe machines; one 26-in. drill, one 20-in. drill and one 14-in. sensitive high speed drill; one woodworker including planer and saw. Each principal machine is driven by individual direct connected motor. One corner of the machine shop is partitioned off for a blacksmith shop and contains a 1600-lb. steam hammer, forge, anvil and tool grinder.

Industrial Gas Masks

The Bureau of Mines announces that it is making a preliminary investigation of gas masks with a view to establishing a list of approved devices for use in the mining and allied industries. After the preliminary investigation the Bureau will issue a schedule of tests which apparatus must meet in order to gain the approval of the Bureau of Mines. These investigations will be conducted at the Bureau's Pittsburgh Station by men who have had intimate connection with the development of mine-rescue apparatus and gas masks.

Gold and Silver Produced in the United States in 1918

The Bureau of the Mint and the Geological Survey have issued the following joint preliminary estimate of the production of gold and silver in the United States during the calendar year 1918:

	Gold		Silver	
State or Territory	Fine Oz	Value	Fine Oz.	Value[1]
Alaska	440,622	$9,108,500	796,836	$796,836
Alabama	36	700	2	2
Arizona	278,647	5,760,200	6,771,490	6,771,490
California	832,389	17,207,000	1,555,417	1,555,417
Colorado	621,791	12,853,500	6,982,313	6,982,313
Georgia	169	3,500	41	41
Idaho	30,764	636,000	10,188,056	10,188,056
Illinois	0	0	8,939	8,939
Maryland	0	0	164	164
Michigan	0	0	491,939	491,939
Missouri	10	200	40,948	40,948
Montana	153,375	3,170,600	15,341,793	15,341,793
Nevada	322,276	6,662,000	10,113,405	10,113,405
New Mexico	30,871	638,200	763,758	763,758
North Carolina	38	800	9	9
Oregon	60,951	1,260,000	150,207	150,207
Philippine Islands	44,202	913,700	12,597	12,597
South Dakota	328,305	6,786,700	165,865	165,865
Tennessee	263	5,400	131,931	131,931
Texas	5	100	612,436	612,436
Utah	152,018	3,142,500	13,439,811	13,439,811
Vermont	47	800	5,117	5,117
Virginia	20	400	2,967	2,967
Washington	16,556	342,300	302,446	302,446
Wyoming	18	400	719	719
Total	3,313,373	$68,493,500	67,879,206	$67,879,206

[1] Valued at the Government buying price of $1 an ounce.

These figures, compared with those showing the production in 1917—gold, $83,750,700; silver, 71,740,352 ounces—indicate a reduction in the output of gold of $15,257,200 and in that of silver of 3,861,156 ounces. The output of gold in 1918 was the smallest in twenty years and that of silver was the smallest since 1913.

Ecuador Establishes Crude-Salt Monopoly

The Minister of the Treasury of Ecuador has just published the text of the law making effective the salt monopoly established there by the legislative decrees of Oct. 13, 1916, and Sept. 26, 1918, reports Consul General Goding. This law, after stating that sea salt will be handled exclusively by the Government and consequently will not be let out to the highest bidder, also that proprietors and owners of salt mines may sell only to the Government, fixes the price which the Government will pay and for which it will sell salt in the republic. The law also limits the amount of salt that will be sold to any one person.

Importation of foreign salt is prohibited, "except in case it should appear for any reason to be impossible to supply the republic with salt from the national mines. This proscription does not apply to refined salt, unless the Government should establish refineries for that purpose."

The Executive, however, is authorized to introduce the refining of salt into the republic, investing for this purpose such sums as may be necessary. The law provides that the Executive shall fix the price of the refined salt, taking into account the expenses incurred in refining it.

Resumption of Trade With Serbia and Rumania

By a recent ruling of the War Trade Board, all persons in the United States are authorized, subject to the rules and regulations of the War Trade Board and the import regulations of these countries, to trade and communicate with persons residing in Serbia and Rumania.

Aids to Foreign Trade in the Chemical Industry

MARKED activity has been displayed by the Bureau of Foreign and Domestic Commerce in its efforts to promote foreign trade. Through the appropriations made by Congress this branch of the Department of Commerce, under Secretary William C. Redfield's direction, has broadened out to all parts of the world and has sent trade commissioners, as they are known, to all countries to glean such information as will constitute reports that should be invaluable to American manufacturers along various lines that have been developed in this country, particularly during the war period.

Now that priorities have been raised and appropriations have been made by the operating division of the Shipping Board, particularly for South America, there will be a tendency toward improvement in the export trade.

Many manufacturers throughout this country have been perplexed as to the best method of securing export trade in their particular line. Herewith is published a chart that has been issued by the Bureau of Foreign and Domestic Commerce, dealing with foreign trade promotion, which, if closely studied, will show the information that is available from our own Government that should furnish a general knowledge of the subject, and serve as a guide to the prospective market. In conjunction with the information shown thereon, there is also published a list of the publications, which can be obtained by writing to any of the district offices or to Washington, specifying the line of information sought.

Recent appropriations have been granted to this department and the service will still be carried out; and through their medium, known as the *Commerce Reports*, issued daily, they are striving to keep the American public informed on the real conditions as they exist.

It is surprising to learn how little is generally known of the fact that this information has been available from the Government agencies, and it is with a view of furnishing this information and encouraging co-operation with this department of our Government that CHEMICAL & METALLURGICAL ENGINEERING is presenting this chart. This information is available to those interested in obtaining it.

British Import Restrictions

All restrictions limiting importation of sirup, molasses and like articles will be removed Feb. 24, 1919.

The following articles will again be on the list of prohibited imports after Mar. 1, 1919, and can then be imported only under special license:

Aluminium and manufactures of aluminium, including aluminium powder; cement, fatty acids, methyl alcohol, salt, soap, weighing machines, scales and balances of all descriptions.—W. T. B. R. 557.

Acetone

By H. P. Bassett, Ph.D.

FOR several years previous to the war the amount of the acetone made in this country was small, the larger part of our gray acetate of lime being exported to foreign countries, to be used in various industries, like synthetic indigo, acetic anhydride, acetone and other products of a lesser volume, as asperin and the like, in the drug trade.

Practically all of the gray acetate of lime produced in this country at that time was obtained from the distillation of wood, to produce charcoal for the charcoal iron industry, and was necessarily dependent on the sale of the charcoal to make the industry pay. For this reason, shortly before the outbreak of the war, many of these plants were shut down, but on the outbreak of the war both charcoal iron and gray acetate of lime came into great demand. Every one is familiar with the extreme test the English Government underwent in its search for acetone to use as the solvent in the manufacture of cordite. Several new plants were built and old ones enlarged to produce the acetone which had been demanded over night, as it were.

New sources of this material were developed, such as the fermentation of molasses to alcohol and the alcohol to acetic acid, the fermentation of kelp and the transformation of acetate into acetone and similar solvents.

The almost exclusive use of acetone during the war was in the manufacture of military explosives, especially for the English Government, and consequently any other use was practically prohibited.

In this search for acetone, one source of this material seems to have been overlooked, namely, that from wood, sugar, gums, etc., mentioned by Freny. (Ann. Chim. 59-7). Freny mentions a source of acetone from the distillation of the above products, especially wood, with eight parts of lime. This does not look attractive on account of the large amount of lime required, but several years ago I had occasion to investigate this problem and much less lime is needed, if the proper conditions are observed.

In order to obtain the best results the mixture of lime and sawdust or wood in a similar state should not be heated too rapidly, requiring about ten hours to reach the maximum heat, and again the vapors should be removed from the retort as quickly as possible after they are formed. This may either be done by steam or an inert gas, such as carbon dioxide, preferably steam. Under these conditions a good yield of acetone and higher ketones can be obtained with 2½ parts of lime to one part of dry wood.

Under the above conditions a yield of 26 per cent of acetone and mixed ketones can be obtained, and as the higher ketones are now in demand and in many respects for certain purposes it is desired to have a solvent of the nature of acetone and one that is not so extremely volatile, these higher ketones are preferable. For many purposes, like films for aëroplane dope, etc., where the evaporation of the solvent is wished to be retarded, the higher ketones find an extended use.

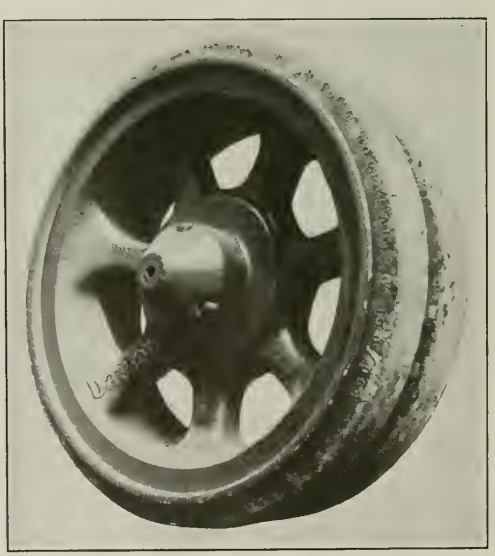
This, however, as a permanent industry has the same disadvantages as that recently mentioned in one of the late numbers of this journal[1] in an article by Tomlinson, entitled "Wood-Waste as a Source of Ethyl Alcohol."

It is entirely possible to use sulphite waste liquors in this same manner, as they can be easily evaporated to a thick or rather thick consistency and then by adding the lime will dry this liquor to the point where it can be dried on a chain drier, drum drier or, better still, in a rotary drier if knockers are provided to keep it knocked from the sides.

The uses for acetone and higher ketones have been greatly extended during the past four years and promise to afford many new outlets for such solvents as, for instance, in the waterproofing of cloth and artificial leathers.

Electric Steel Castings

WHEN the modern motor truck first made its appearance in the business world, it was in many ways still a rather crude affair. But constant improvements and changes have developed it, until to-day it is one of the most effective methods of commercial transportation. One of the latest of these improvements has been the invention of a one-piece steel wheel for motor trucks. The constantly increasing weight of loads and the high speed which have been demanded of the motor truck proved too great a strain on the old-style wheel of the built-up type. A loose spoke on a motor truck wheel was found to be a much more serious matter than



ONE-PIECE STEEL WHEEL FOR MOTOR TRUCKS

it was in the days of the horse and wagon. "Flats" which developed were very destructive of bearings and axles and, in fact, had a destructive effect on the entire structure of the truck.

Automotive enginers, who were quick to see this trouble, studied the matter carefully. It was universally accepted that a metal wheel was the proper type

[1] Chemical & Metallurgical Engineering, Vol. 10, No. 7, Oct. 1, 1918.

for motor truck use and would meet the great need of strength. As a result numerous styles and types of metal wheels were evolved in an effort to build a wheel which would answer every requirement of truck haulage. While these different types of metal wheels were each an improvement in certain ways over the old-style built-up wheel, they were lacking in two or more of the essential qualities.

The ultimate wheel, which answers every requirement and which is finding great favor among manufacturers of motor trucks and among truck owners, is the Dayton steel wheel. This is a one-piece wheel of electric furnace steel. It at once overcomes any possibility of loose spokes, because of its one-piece construction. Spokes and rim are hollow and of uniform thickness, which result in lightness of weight that is astonishing. As will be noted from the illustration herewith, it has also a peculiar construction in its odd number of spokes and sweeping curves. This design has the effect of dissipating excessive road shocks so that they do not reach the axle, but are distributed throughout the wheel, which greatly prolongs the life of the truck.

Recent Government tests have proved that the Dayton steel wheel has remarkable strength and resiliency. And the fact that Government experts were impressed with the advantages of this style of wheel is evidenced in the specification of steel wheels of this type in the construction of motor trucks for war work.

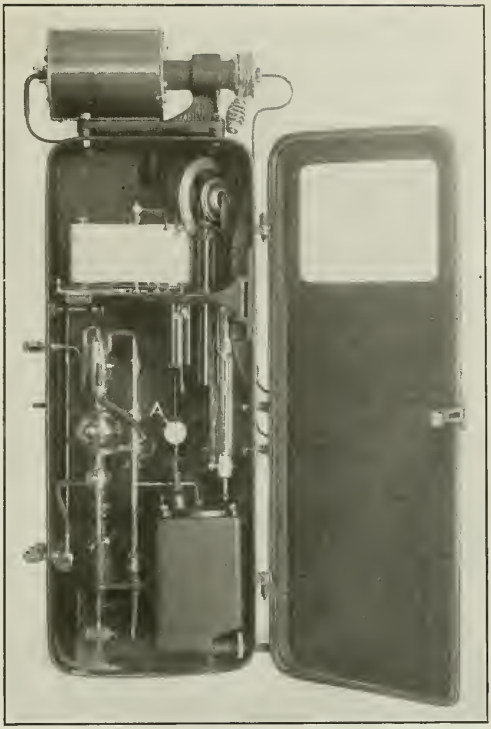
An extensive national advertising campaign which is now being conducted on this wheel is arousing a great deal of interest among manufacturers of motor trucks and among users. There is bound to be a wide use of the Dayton steel wheel for motor trucks.

Hydrogen Recorder

THE Harger hydrogen mono recorder is adapted for almost all industrial purposes, as a variety of ranges are provided. Similarly to the Mono CO_2 recorder, an auxiliary apparatus which also analyzes automatically carbon monoxide, methane, carbon dioxide and oxygen can be attached to this instrument.

Briefly the principle of the hydrogen mono is as follows: The gas is trapped off in a 100 cc. burette by means of a falling mercury column. The motive power of the instrument can be either water or compressed air. When the sample is thus trapped off, it passes into an electric oven in which there is inserted a cartridge which at high temperature oxidizes the hydrogen in the gas to water. This water vapor follows the gas sample, is condensed and removed. Thus contraction is brought about in the gas mixture and as at the same time the original volume is altered according to the amount of hydrogen absorbed, the change of this volume is recorded in the usual manner on a sixty days' chart of such width that each per cent and fraction thereof can be plainly read with accuracy. The electric oven requires about 200 watts and is made for a voltage of 110.

The oxidation cartridge is gradually reduced and arrangements are made for convenient replacement. The cartridge may also be regenerated by heating. Its durability depends upon the amount of carbon dioxide and methane in the gas analyzed. The smaller the amount of hydrogen the longer it will last, and on an average of 10 per cent of hydrogen and a speed of thirty analyses per hour the cartridge will retain its full strength for about two hundred hours. There is no other maintenance cost connected with the instrument and it should, therefore, be considered as a very important addition to the chemical plant equipment put out by the F. D. Harger Co. of Buffalo.



HYDROGEN MONO RECORDER

Ordnance Scrap Material for Sale

The War Department authorizes the following from the office of the director of sales:

The estimated value of ordnance scrap material on hand Dec. 31, 1918, by classes has been reported by the stores and scrap section of the Ordnance Department to the director of sales. The list is as follows:

	Pounds
Aluminium scrap, all kinds	46,608
Brass scrap, all kinds	5,842,351
Cupro-nickel scrap, all kinds	781,392
Copper scrap	691,580
Machine shop borings and turnings	9,714,139
Steel, heavy melting, scrap	20,771,061
Steel, low phosphorus, scrap	5,988,477
Nickel steel, heavy melting, scrap	5,518,359
Nickel steel, borings and turnings	15,654,919
Cast and malleable iron, scrap	13,692,718
High speed borings, turnings, scrap tools	63,365
Mixed and miscellaneous iron and steel scrap	5,195,748
Miscellaneous scrap, consisting of rags, waste paper, etc.	803,956
Lead dross scrap	153,005
Lead scrap	322,355
Brass ashes and sweepings	1,067,571
Burlap	256,963
Spent acid	1,495,250
Amatol	269,847
Ammonium picrate	5,000
Tetryl	18,660
Total	88,352,324

It should be noted, however, that scrap inventories vary every day.

Synopsis of Recent Chemical and Metallurgical Literature

Slagging Gas Producer.—A description of the slagging gas producer working on coke was recently republished in the *Iron and Coal Trades Review* from *Stahl und Eisen*. It is a short blast furnace, with a relatively deep hearth, 5 ft. 3 in. in diameter, a shallow bosh, and a vertical shaft, the whole being 16 ft. 5 in. high. Sufficient high-iron slag from a mixer or a basic open-hearth is charged with the coke to be gasified in order to properly slag its ash—30 tons of coke being charged in 24 hours. The blast is warmed in a heat interchanger to 70 deg. C., and blown through water-jacketed tuyeres at 15.7 in. water pressure. Slag is tapped at four-hour intervals, while 8 to 12 hours are required to accumulate 8 in. of iron in the bottom of the hearth. The iron produced contains 8 to 10 per cent of manganese and somewhat more phosphorus. The top of the producer is covered by a flat dome of refractory brick, pierced by numerous peep holes. In operation no poking or stirring is necessary, the gas leaves the shaft at about 700 deg. C., is practically free from tar, and has the following analysis:

CO_2	0.3 to 0.7
CO	33.0 to 33.5
CH_4	1.2 to 1.3
H_2	0.1
H_2O	12 g. per cu.m.
S	0.28

The coke contained 84 to 88 per cent carbon, with a calorific power of 7000 calories, while the yield of the above gas amounted to about 175,000 cu.ft. per British ton. This producer has been operating satisfactorily at the Georgesmarienhütte for over two years, working for thirteen months continuously before the lining of the hearth had to be removed.

The Elastic Indentation of Steel Balls Under Pressure.—C. A. Briggs, W. C. Chapin and H. G. Heil of the Bureau of Standards have studied the effect of pressure on the steel balls and rounded-end length standards used for munition gages. For the light pressures studied they conclude that the deformation of the ball-surface not actually in contact is very small. They therefore confined their attention to measuring the area of contact made by flat and spherical surfaces, one of which was of transparent glass. This area was the central spot in the system of Newton's rings formed in each case. From experimental and theoretical considerations, the following general formula was derived which gave very excellent results:

$$\Delta G = 0.518 P^{\frac{2}{3}} \left[\frac{G_1 + G_2}{G_1 G_2}\right]^{\frac{1}{3}} \left[\frac{1}{E'_1} + \frac{1}{E'_2}\right]^{\frac{2}{3}}$$

Here ΔG = the mutual indentation between the surfaces in contact; P = the pressure acting between the two surfaces; G_1 and G_2 = the radii of curvature of the two surfaces; E'_1 and E'_2 = the indentation moduli of the surfaces G_1 and G_2.

The indentation modulus is given by the expression

$$E' = \frac{E}{1 - u^2}$$

where E = Young's modulus; u = Poisson's ratio.

The case of the indentation of steel balls between flat steel surfaces appeared to have the most immediate importance. Consequently the following special formulæ were derived, using tabular values for the physical constants involved. For precision work it would of course be necessary to determine Young's modulus and Poisson's ratio for the materials in hand, as well as to check the

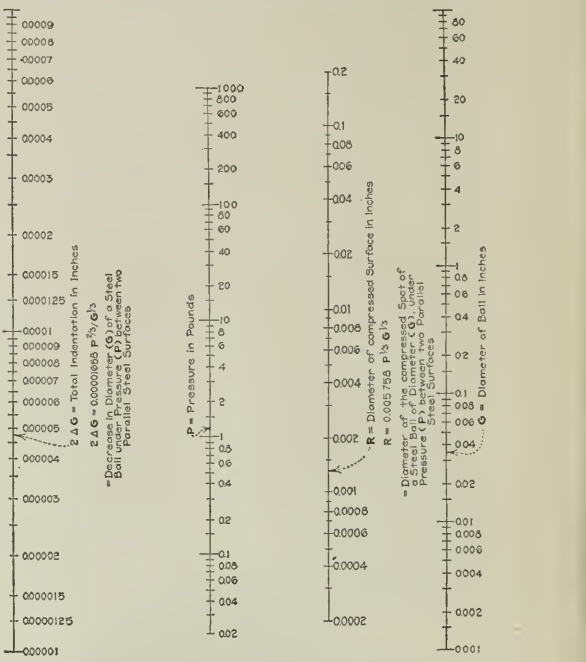


FIG. 1. INDENTATION OF STEEL BALLS

extrapolation of the general formula from the very low pressure used by the authors (20 pounds pressure on ⅜- and 1-in. balls) to the region in use.

Indentation for Steel Balls Between Flat Steel Surfaces:

$$2\Delta G = 0.0000166 \frac{P^{\frac{2}{3}}}{G^{\frac{1}{3}}}$$

where $2\Delta G$ is given in inches.

Diameter of Area of Contact Between the Surface, Steel Against Steel:

$$R = 0.00576\ P^{\frac{1}{3}}\ G^{\frac{1}{3}},$$

where R is given in inches.

Average Pressure Over the Area of Contact, for Steel Against Steel:

$$S = 38.400 \frac{P^{\frac{1}{3}}}{G^{\frac{2}{3}}}$$

where S is given in pounds per square inch.

Fig. 1 gives an alignment chart for graphical solution. A straight line drawn between any two points determines corresponding values on the intercepts with the other axes.

Divorce of Pearlite After Cold Working.—J. H. Whiteley read a paper before the May meeting of the Iron and Steel Institute (British) giving the results of a research started by the observation that the color-carbon given by a cold-worked sample is considerably higher than the determination on the same metal in

an unstrained condition. A piece of eutectoid steel showing very fine pearlitic laminations was cold-hammered from $\frac{1}{2}$-in. square to $\frac{1}{4}$-in. square. After annealing at 650 deg. C. for one hour it was found that almost the whole of the cementite had been divorced and now appeared in small spheroids. In a fresh piece the laminations showed a decided tendency to break up after annealing for 15 minutes at 500 deg. C., while 15 minutes at 600 deg. caused almost complete divorce. Considerable difference in speed of the transformation in various portions of the areas was noticed, however. In order to discover the relation of the degree of deformation to the speed of spheroidizing, a $\frac{1}{2}$-in. bar was struck lightly twice, reducing its cross-section to about $\frac{7}{16}$ in. Two hours' annealing at 680 deg. showed only traces of the original laminations. The authors suggest that this acceleration of divorce on annealing may prove to be a delicate test for small amounts of strain in pearlitic steel. Coarse pearlite in low carbon steels gave the same results as above. The spheroidal pearlite obtained after cold working and annealing cannot be distinguished from the "granular pearlite" of quenched and tempered steels; the two probably are identical in structure.

As is well known, to bring about this result in unstrained steel requires many days' heating. It is not thought that the cold working ruptures the cementite laminæ, thus presenting fragments which later ball up by surface tension. H. LeChatelier's suggestion that the bent laminations are in a state of elastic tension, which state of strain has been shown to increase the solubility of crystals, may have considerable bearing on determining the points where the cementite layers first part.

Again, cementite films are known to be in a metastable condition. Goerens has also shown that the strain in iron due to cold work is removed rapidly at the same temperature at which rapid divorce starts. It is very possible that the slight changes in volume, crystallization and surface tension accompanying relief of internal strain may disturb the metastability of the cementite laminæ, resulting in accelerated spheroidizing.

Finally, the author suggests that the false stability of the films of cementite is disturbed by working, and it breaks up much as does a thin cylindrical stream of water issuing from a tap when subjected to slight vibrations.

Heat-Treating Shells.—A paper was read before the Steel Treating Research Society at Detroit in March, 1918, by J. M. HALL, giving the methods of heat-treating shells used at the Hamilton Steel Wheel Co. of Hamilton, Canada. The chemical and physical requirements for the principal shells are:

	18-Lb. British Shrapnel $3\frac{1}{2}$-In. Blanks	Finished Shell	6-In. High Explosive
Carbon	0.48 to 0.60	.....	0.40 to 0.55
Manganese	0.5 to 1.0	.....	0.60 to 1.0
Silicon	Under 0.3	.....	0.15 to 0.35
Phosphorus	Under 0.06	.....	0.0 to 0.05
Sulphur	Under 0.05	.....	0.0 to 0.05
Elastic limit, lb.	42,600	80,700	More than 42,600
Ultimate, lb.	78,500	126,000	78,500 to 110,000
Elongation, per cent.	20 in 2 in.	8 in $\frac{1}{2}$ in.	14 to 30 in 2 in.

After finish-boring and rough-turning the rolled bars used for these shells they are ready for the quenching operation. Heating is effected in an oil-fired furnace with a combustion chamber underneath the hearth. The shells are ranged into the furnace on end, and slowly heated to from 1500 to 1700 deg. F. depending upon the carbon content. The hot shells are then quenched in a soluble oil. A very handy tank for this operation, especially in automatic furnaces, consists of a round bath, 7 ft. in diameter and 3 ft. deep. Inside this bath is a turntable containing a series of baskets into which the hot shells are dropped and remain upright, base downward. The turntable slowly rotates, and the quenched shell is withdrawn on the opposite side after immersion for about 6 minutes. The average oil temperature is kept below 200 deg. F. by circulation over cooling coils. After quenching, the shells are drawn in a similar furnace to a temperature of from 950 to 1350 deg. (depending upon the carbon content) and air cooled. The open end is immediately heated to 1100 deg. F. in a metal bath, "nozed," and immediately buried in flake mica for slow cooling.

High explosive shells are forged from open-hearth steel blanks. For instance, a 6-in. shell is made from a blank cast on end in a preheated cast iron mold with a hot top, $6\frac{7}{16}$ in. in diameter, tapering at the bottom. The metal is poured slowly through a 1-in. nozzle to minimize piping. The hot castings are stripped, 20 per cent of the top of the blank is cut partly through and then broken. This discards the piped top and gives a fracture for inspection. Forgings from properly cast blanks give as good results as those from rolled bars. The bars are heated for forging in a flat-hearth, oil-fired furnace, 7 ft. by 14 ft. in dimensions, with a capacity of 100 6-in. shells. It requires $2\frac{1}{2}$ hours to complete a furnace cycle, the steel being held at the correct heat (1800 to 2000 deg. F.) at least 15 minutes, since it is important that the interior of the bar attain the correct temperature and that the forging be done on a cooling piece of metal. Forging is done in various ways: The billet may first be pressed into the die—an operation called "bunting"—pierced large, and the whole then drawn through a succession of rings to reduce the size to the proper dimension. As an alternative method, the shell may be bunted and pierced to size, or finally a round billet may be pierced to size in one operation. The last method is now usual practice in Canadian shops and apparently gives as good results as the two others. After forging, the temperature is about 1700 deg. F., and the shell is cooled on a slow-moving conveyor leading through a draft tunnel. The time required to reach a temperature of 800 deg. F. is from one to two hours, depending upon the carbon content of the shell. About 2 per cent of the forgings are then selected for physical tests, and test bars are cut from the base end by an acetylene torch.

If the shells are rejected as having too high an ultimate strength they are annealed to 1600 deg. F. and allowed to cool in the furnace. This practice will reduce the ultimate of a 60-point steel 7000 pounds and increase the elongation 6 per cent. On the other hand, low carbon steels which are rejected for opposite causes are heated to 1550 deg. F., placed on rollers under three pipes blowing air at 12 oz. pressure upon them through a number of holes. The shells are cooled to 800 deg. F. in 7 minutes, while the ultimate strength is raised 8000 pounds with a corresponding reduction of the elongation of only 0.6 per cent. In this manner the final rejections at the plant in question have been reduced to less than 1 per cent.

Book Reviews

SCRAP METALS. By *George H. Manlove* and *Charles Vickers.* 278 pages; price $2.00. Cleveland, Ohio: The Penton Publishing Co.

The authors point out that although scrap occupies a place as one of the most important raw material departments of the iron and steel world, the scrap industry has had no literature. They state that the present effort to present a broad review of the business originated in a series of articles recently printed in the *Daily Iron Trade and Metal Market Report.*

The book is divided into two parts, the first of which, by Manlove, treats of steel and iron scrap, while the second, by Vickers, treats of non-ferrous scrap. In the first section of the book the author discusses the importance of the scrap industry and throws much light on the conventional classification of scrap, including specifications for scrap intended for various special purposes; methods of collection as practiced by the producers in industries in which scrap metals are by-products, and by scrap dealers, large and small, are described in outline; and an account is given of the methods of organization in current use as well as conditions governing price regulation. These features are sufficiently developed to make the book extremely useful to all persons who are either directly or indirectly interested in the purchase or sale of scrap.

In this country, until within recent years, waste has proceeded in many industries without hindrance. Since the war the widely advertised salvage operations on warfronts by the belligerent Powers have aroused new interest in the possibilities of such operations as applied to American industries. As a consequence there are now appearing in trade journals detailed descriptions of the procedure at present followed in certain plants. This book gives an interesting summary of some of the efforts which have been made in this country, especially by railroad companies. This account should make the book well worth reading for persons not especially interested in scrap because of the suggestions for the reclamation of waste which can often be carried over bodily to other industries. The author has succeeded in presenting his subject in such an interesting manner that reading for this purpose by such persons will not be difficult.

The second part of the book, which deals with non-ferrous scrap metals and alloys, is briefer, but, like the first part, contains much valuable information and suggestions concerning the reclamation and disposal of such materials.

Both of the authors are to be congratulated on producing a useful book on this important but hitherto neglected subject.

Personal

Mr. C. N. Barney has been appointed representative for the Worthington Pump & Machinery Corporation of Virginia at the New York office, 115 Broadway.

Prof. W. D. Bonner, professor of chemistry at the University of Utah, is also acting as consulting chemist to the U. S. Bureau of Mines and is in charge of laboratory investigation on oil shales.

Mr. Arthur F. Braid has been appointed sales manager of the metal and alloy department of the Metal & Thermit Corporation, New York City.

Mr. Frederick K. Brunton is now with the Phelps-Dodge Corporation's smeltery at Douglas, Ariz., having recently left Morenci, Ariz.

Mr. F. W. Bunyan is now chief chemist of the Noble Electric Steel Co., Heroult, Calif.

Dr. E. E. Charleton, assistant in chemistry at the University of Illinois, has resigned that position to accept one with the du Pont Powder Co. of Wilmington, Del. He will be succeeded by Lieut. J. B. Brown, who has recently been released from military duty at the Chemical Welfare Service, Washington, D. C.

Captain R. L. Kramer, C.W.S., who has been officer in charge of the men in uniform at the War Laboratory, Johns Hopkins University, Baltimore, Md., has been released from service and has entered as a graduate student in chemistry at Johns Hopkins.

Mr. C. E. Littell has resigned his position as chief chemist of the Providence Gas Co., to take charge of the heating of the new Koppers by-product coke and gas ovens. Before going to Providence, Mr. Littell was connected with the United Gas Improvement Co. of Philadelphia, Pa.

Mr. J. J. McKee has severed his connection with the C. A. Dunham Co., Marshalltown, Ia., to accept a position with the Machinery Utilities Co., 501 Fifth Ave., New York City.

Mr. H. C. Parmelee, editor of Chemical & Metallurgical Engineering, was elected an honorary member of the Teknik Club of Denver at a meeting held on Jan. 14. Mr. Parmelee was secretary of this society for some years, at which time he was Western Editor of this journal with an office in Denver.

Lieutenant Lloyd Van Doren, C.W.S., who was formerly in General Sibert's office in Washington, D. C., has accepted a position as Carnegie assistant under Mr. Frazer of the Johns Hopkins University, Baltimore, Md., and will work for the remainder of the year on osmotic pressure.

Captain Gerald L. Wendt, who was discharged from the Chemical Welfare Service on Dec. 1, has taken up his duties again as assistant professor of chemistry at the University of Chicago and as a member of the editorial board of the Bulletin of the Chicago Section of the American Chemical Society.

Mr. Harry J. Wolf of the Malm-Wolf Co. has been appointed consulting mining engineer in the U. S. Bureau of Mines.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, Feb. 8. — Liberal price concessions have been made but no heavy buying has resulted.

Aluminium:—The Government prices on ingots 98 to 99 per cent Al are $660 a ton f.o.b. plant in 50-ton lots; $662 down to 15-ton-lots; and $666 down to 1-ton lots, which prices will continue until the first of March. Prices per pound for small lots vary from 40c. to 45c.; sheet aluminium, 18 ga. and heavier, 42c.; powdered aluminium, 100 mesh, 70c.

Antimony:—Antimony continues to sell at from 7⅞ to 7½c. per lb. with no changes in view.

Copper:—The situation in the copper market is extraordinary. Sales at 18¼c. have been made, but stocks are still accumulating.

Copper sheets, hot-rolled	lb.	$0 29	$0 33
Copper sheets, cold rolled	lb.	.30 —	.34
Copper bottoms	lb.	.37 —	.41
Copper rods	lb.	.25½	
Copper wire	lb.	.23	
High brass wire	lb.	.24½ —	.26½
High brass sheets	lb.	.24½ —	.26½
High brass rods	lb.	.23½ —	.25½
Low brass wire	lb.	.26½ —	.28½
Low brass sheets	lb.	.26½ —	.28½
Low brass rods	lb.	.27½ —	.29½
Brazed brass tubing	lb.	.35½ —	.37½
Brazed bronze tubing	lb.	.40½ —	.42½
Seamless copper tubing	lb.	.35 —	.37
Seamless bronze tubing	lb.	.40½ —	
Seamless brass tubing	lb.	.34 —	.36
Bronze (gold) powder	lb.	1.00 —	1.75

Lead:—This market is stagnant even at 5c. quotations, but the validation of informally made war contracts will soon reawaken activity.

Tin:—The U. S. Steel Products Co. has liquidated 3000 tons of the original 10,000-ton stock at the 72c. basis. It is expected that it will take several months to dispose of the remaining stock, after which prices will fall sharply.

Zinc:—Spelter has fallen with spot New York at $135 per ton and futures at $128. East St. Louis spot is quoted at $128.

OTHER METALS

Bismuth	lb.	$3 50 —	$3 65
Cadmium	lb.	1 50 —	
Cobalt	lb.	2.50 —	3.50
Magnesium	lb.	1 75 —	2 10
Mercury	75 lb.	95 00 —	
Mercury	lb.	1 95 —	
Nickel	lb.	40 —	45
Tungsten	lb.	Nominal	
Iridium	oz.	175 00 —	
Palladium	oz.	135 00 —	
Platinum	oz.	105 00 —	108.00
Silver	oz.	1 01½—	

The Iron and Steel Market

Any doubt that may have existed as to the character of the iron and steel market, for the first half of 1919 at least, has now been dispelled by the continued inactivity and by the failure of any signs to develop that favorable conditions are on the way.

During the latter part of January buying of steel products was at a slightly increasing rate, though at the best it was light. In the past fortnight the market has been even more stagnant than formerly.

Steel mill operations have been at an average of about 50 per cent of capacity in the case of the independents, while the Steel Corporation subsidiaries have been operating at about 85 per cent. The difference in rates is not to be ascribed to difference in the character or volume of business on books, but is rather to be attributed to a difference in policy. The independents are making only the material for which they have shipping orders, while the Steel Corporation is putting a considerable portion of its output into stock. At the pipe, wire, sheet and tin plate mills there is storage capacity equal to from four to six weeks of production, and for these products as well as for bars, shapes and plates the Steel Corporation has a line of warehouses from Boston to Chicago and New Orleans. By the close of the war stocks at these warehouses had been reduced to almost nothing. Apparently the Steel Corporation is actuated not so much by a desire to have a reserve of material against increased demand in future as by a desire to give employment to its men, preventing discontent and discouraging the spread of union sentiment, for unionization of the steel industry, on account of its tendency to restrict output, would be extremely harmful.

Economies in Production

While there is economy, as to production cost per ton, in operating at 85 per cent rather than 50 per cent, not a great deal of attention is paid to economies as disclosed merely by the cost sheet, for matters of policy are involved. Thus with basic pig iron held at $30 at furnace and with heavy melting steel available at $16 a ton or thereabouts it would undoubtedly be cheaper to use large percentages of scrap and cut down the consumption of pig iron, and this would apply to a great extent even to the self-contained interests, whose production cost of pig iron is to be considered, rather than the open market price, yet there is no evidence that the proportions of scrap used have increased. Scrap is, indeed, a drug on the market and dealers doubt whether the mills are using as large a percentage as formerly in their open-hearth charges.

Character of Demand

Demand for steel products is entirely along lines of everyday consumption, orders involving permanent construction or investment works being very conspicuous by their absence. Manufacturing consumers generally, making various wares practically for sale over the counter, are buying in a moderate way, but with great conservatism and evidently with a view of maintaining stocks at the lowest possible point. This is true also of jobbers, who buy only for immediate turnover. The automobile makers are taking steel very freely and already have almost attained their former rate of consumption. The buying of electrical sheets is almost entirely confined to material for automobile equipment, indicating that electric motors and generators of large size are in no request, a condition that does not obtain when there is new construction work in progress or in sight, such as involves demand for structural and cognate forms of steel. The agricultural implement makers are taking steel at a fair rate, evidently in expectation of at least moderate demand from the farmers, and steel producers are in expectation of the farmers buying fairly well of fence wire, wire fence, wire nails and sheets, though thus far such buying has been very far from heavy.

Barriers to Activity

Conditions in the steel trade are not peculiar to that industry, but are to be found more or less in industrial activity generally. The barriers to activity apply in particular to works of construction, of the investment character, and as steel passes largely into such permanent works, rather than into items of current consumption, the condition is most pronounced in steel.

The two great barriers to activity, of course, are the failure of prices, or costs, to adjust themselves to prospective conditions, and the menace of bolshevism. Both are equally deterrent influences to the prospective investor, who does not wish his investment to be destroyed or have its earning power reduced, as a spread of bolshevism would threaten, while a decline in the cost of construction work would write a depreciation upon any work completed at the higher cost, and thus tend to decrease its earning power.

The two barriers, high costs and the bolshevist menace, are closely interwoven. The bolshevist menace discourages attempts to reduce costs, although in the long run that would be to the advantage of labor, as it would produce more work.

Steel Industry Helpless

In the circumstances the steel industry is helpless. It cannot bring about better conditions, for the barrier to steel consumption is neither the character nor the price of the steel that is offered for sale. It is the cost of putting steel into consumption, and the uncertainty of reward to the investor after he had put the steel into employment, that prevents buying. It is true that current prices for steel products are too high to furnish a proper basis for a widespread demand, but adjustment in that matter can be effected when it becomes apparent that the need is arising. To cut prices now, little or much, would not increase demand for a time at least, and would indeed at the outset prove discouraging to buyers. With reduced operations mills need very considerable profits per ton to maintain their position, and for the mills to lose money would benefit no one. Of course the salesmen of the steel companies endeavor to prove to customers that steel prices are unlikely to come down much if at all and indeed really simply can't come down much, but such arguments are of only temporary use. There can be scarcely and doubt that eventually, and before there is such a demand for steel as to engage the full mill capacity, there will be very considerable declines in steel prices. The pre-war average will not be attained, but more than half the distance from Government prices of 1918 to the pre-war average will in all probability be traversed.

Prices Firm

Finished steel prices are firmly maintained at the declines that became effective in December, from the Government limits: Plates, 3c.; shapes, 2.80c.; bars, 2.70c.; grooved steel skelp, 2.70c.; blue annealed sheets, 10 gage, 3.90c.; black sheets, 28 gage, 4.70c.; tin plate, $7.35; standard steel pipe, 54 per cent basing discount. Wire remains at 3.25c. and wire nails at $3.50, the Government limits. Billets are $43.50, sheet bars and small billets $47, slabs $46 and rods $57.

Pig iron prices are likewise firmly maintained as follows: Bessemer, $32.20; basic, $30; No. 2 foundry, $31; malleable, $31.50; forge, $30. These prices are, in general, f.o.b. furnace, and represent $3 reduction from Government limits.

Producers experience no difficulty in maintaining prices, as there is no temptation, by way of business offered, to cut prices.

Chemical Market

COAL TAR PRODUCTS:—The position of coal-tar products is somewhat easier and reports from most directions would indicate trading on the whole is in reasonably good volume, but individual sales are of a minor character and buying is still along conservative lines. Buyers are seemingly holding back, anticipating a further decline in prices before bringing their full requirements to the market. Producers are in full accord with this situation, but maintain that their present prices reflect sufficiently well, in view of the costs in production, claiming that labor and raw materials are still maintained at high levels. Among the crudes benzol shows the same steady trend, with trading in reasonably good proportions. Phenol remains in an unsettled condition, while toluol holds close to the levels heard for some time past.

Benzol:—Producers of this commodity have not altered their recent quotations and the situation remains in strong hands with only occasional lots appearing in the resale market.

Phenol:—Trading in this commodity has developed to no unusual proportions, with quantities of the product reaching the resale market at prices as low as 11c. and sales are reported to be passing at this figure.

Toluol:—Consuming demand continues along quiet lines, with offerings through second hands being made at prices 2c. below manufacturers', who have made no changes in their recent quotations.

Dinitrochlorbenzol:—Trading in the general market is in small lots and supplies seem to have accumulated but in no important quantities. Manufacturers have reduced their prices 5c. per pound.

Alpha Naphthylamine:—Price changes to extent of 2c. per pound have been made, but this cut has seemingly had no effect in stimulating business and available supplies are more than sufficient for the current call.

Orthotoluidine:—The market for this commodity has been without special feature for some time back and the continued indifference on the part of consumers is still in evidence. Stocks are in considerable quantities, but prices have not changed since the recent decline.

Dinitrophenol:—There has been a little increase in the general demand for this product since the reduction in the selling schedules last week, but at the present trading is confined to small lots.

Dinitrotoluol:—The lack of consumption requirements has brought about an easier situation so far as stocks are concerned, but prices remain quotably unchanged.

Metanitraniline:—Supplies of this material which are reaching the market are none too liberal, but on the other hand the demand is in proportion, therefore the situation is met without difficulty and prices are firm.

Mixed Toluidine:—A satisfactory movement is generally reported for the product, but individual sales are in small lots and indicate buying is carried along on conservative lines. Prices have not been subject to any material change since the recent decline.

Beta Naphthylamine:—While there is no pronounced activity in this market a fairly steady business is evident, with stocks fully in proportion to the current call and prices are firmly maintained.

Diphenylamine:—The product presents a quiet appearance, with no important interest noted in any single direction. Despite this quietness prices remain at the same firm levels.

Paraphenylenediamine:—Supplies of this material are in fairly good quantities and trading is along conservative lines, but of sufficient volume to take the slack off the market. Dealers who are offering have not altered their recent prices for the various grades.

HEAVY CHEMICALS:—There was not much snap in business during the interval, although there was a fairly good demand evident for some of the items for export purposes, but dealers are looking forward to a larger volume of trading in this direction. Second hands seem to be in full control of the market, which is general during this period of the year, in view of the carry-over of stocks, but manufacturers seem to be more inclined to meet this situation, making an effort to bring about a more equitable condition, although dealers seem to be so overstocked with many of the heavy chemicals that price cutting is active and the entire situation favors the buyer. For instance, bichromate of soda sold in the resale market at 13c. on spot, caustic soda and soda ash sales were consummated at some low levels. Price conditions on the spot were such that pressure on the part of sellers, second hands, developed to such an extent that many of the items were subject to a decline, but this apparently had no effect on stimulating additional business.

Soda Ash:—During the latter part of the week single bag ash was subject to a more active inquiry, but actual transactions were of moderate proportions, with sales being consummated at $1.40 per hundred pounds from the warehouse. Odd lots of barrel material were sold at $1.65 ex-warehouse, with the general quotation ranging from $1.75 to $1.85 per hundred pounds. Double bag ash in the Middle West was subject to virtually no call, therefore exporting of this product has developed to a nominal position.

Caustic Soda:—Odd lot trading seems to have been the feature of this market and the sales noted during the week were for export material, which was sold at prices ranging from $3.20 to $3.25 per hundred pounds f.a.s. Offerings from the warehouse were being liberally made at $3.05 per hundred pounds ex-store, while some scattered lots of material were offered at $3.10 to $3.20 f.a.s. Ground caustic was subject to no unusual call, with offerings by first hands being made at $4.50 per hundred pounds ex-store, while resale material was available at $4.15.

Bleaching Powder:—Comparatively little is heard from buyers of this commodity and the sales noted would indicate purchasing is along conservative lines. However, a fair movement is experienced for export purposes, although demand in this direction is not of such proportions that any difficulty is experienced in meeting the situation. Manufacturers are quoting large domestic drums from works at 2c. per pound, while this price is shaded by second hands for spot goods. Export drums at the works are offered by producers at 2¼c. per pound, with material in the resale market being available at 3c. f.a.s.

Yellow Prussiate of Soda:—Offerings of the material have reached the resale market at prices as low as 26c., with some sales passing at this figure, while the general market quotation ranges from 27c. to 28c.

Permanganate of Potash:—The continued lack of demand has brought about a steady decline in prices for this product, with virtually no interest in the technical variety, and sales for the U. S. P. grade were noted at 95c. per pound. Buyers are seemingly interested in only such lots as are needed for immediate use. Resale lots were offered at prices ranging from $1.00 to $1.05 per pound for the U. S. P.

Bichromate of Soda:—Quiet trading in addition to keener competition among holders who show some anxiety to sell has brought about prices as low as 13c. with actual sales noted at this figure. There were offerings throughout the market at prices ranging from 13½c. to 15c. ex-store.

Chlorate of Potash:—Export trading in this commodity has been sufficiently active to maintain a rather firm market, with no disposition on the part of holders to shade the price of 40c. f.a.s., although there were offerings of the Japanese product at 33c. per pound ex-warehouse.

Cyanide of Soda:—Consuming requirements seem to be sufficient to keep the position of this item firm and available supplies are none too liberal. However, there has apparently been no difficulty experienced in filling orders. Prices are steady at 30c. to 31c. per pound.

Hyposulphite of Soda:—A rather firm situation continues for this item, although the demand is not persistent, but on the other hand stocks are none too liberal in supply. Sellers quote on the former basis of $3.60 for the pea crystals and $3.25 for the regular crystals, per hundred pounds.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET FEB. 8, 1919

Acetic anhydride	lb.	.90 —	1.00
Acetone	lb.	.15½ —	.16
Acid, acetic, 28 per cent	cwt.	3.25 —	3.50
Acetic, 56 per cent	cwt.	6.50 —	6.75
Acetic, glacial, 99½ per cent, carboys	cwt.	14.00 —	14.50
Boric, crystals	lb.	.13½ —	.15
Citric, crystals	lb.	1.25 —	1.27
Hydrochloric, (22°)	cwt.	2.50 —	3.00
Hydrofluoric, 30 per cent, in barrels	lb.	.08 —	.08½
Lactic, 44 per cent	lb.	.14 —	.15
Lactic, 22 per cent	lb.	.06 —	.07

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

CLIFTON.—J. Cristy, lessee of the Lazinsky group of mines between Clifton and Metcalf, will build a 250-ton mill at the copper mines here.

GLOBE.—The Gila Monster Mining Co. will build a 50-ton cyanide mill for its Richmond Basin property, seven miles north of here. W. H. Seamon, superintendent.

OATMAN.—The Mossback Mining Co., Kingman, will build a milling plant here this year. Estimated cost, $400,000.

California

OXNARD.—The city trustees plan an election to vote on $140,000 bond issue for the construction of a gas plant.

TURLOCK.—The city trustees contemplate the construction of a new sewage disposal plant. Plans for same have been submitted to the Board of Health for approval.

Colorado

MONTROSE.—J. N. McBride, representing a syndicate of Colorado and Michigan mining men, has acquired an option on the Cash In Mine, Montrose County, and will build a flotation mill.

Connecticut

HARTFORD.—The city will build a filtration plant. Estimated cost, $400,000. C. Mills Soville, superintendent of waterworks.

Florida

FORT LAUDERDALE—The city will install softening and filtration plants in connection with the improvements it plans to the waterworks. Total estimated cost, $30,000. H. C. Davis, city engineer.

Idaho

SALMON.—The Harmony Mines Co., 602 Hearst Bldg., Chicago, Ill., will install a concentration plant and mill at their property here. Estimated cost, $45,000. A. W. Nieman, manager.

Illinois

GILLESPIE.—The village plans to build a water system, to include a filter plant, reservoir and pumping station. Miller, Holbrook & Warren, 517 Milliken Bldg., Decatur, engineer.

SPRINGFIELD.—The city will build a sewage disposal plant. Wade Seeley, City Hall, engineer.

WOODRIVER.—The Standard Oil Co. of Indiana, 910 South Michigan Ave., Chicago, will build an addition to its refinery here. C. B. Manbeck, Woodriver, local manager.

Indiana

EAST CHICAGO.—Bids will be received until February 25 by C. L. Kirk, vice-president of the East Chicago & Indiana Harbor Water Co., 113 Monument Circle, Indianapolis, for the construction of a water purification plant, consisting of chemical house, filter house, boiler house and pumping plant addition, sedimentation basins and filtered water reservoir.

Louisiana

BATON ROUGE.—The Illinois Central R.R., Central Station, Chicago, Ill., has awarded the contract for the construction of a one story, 25 x 40 ft. filtration plant, having a capacity of 25,000 gallons per hour, to the Graver Tank Works, 4809 Todd Ave., Chicago, Ill. Estimated cost, $18,000.

Maryland

BALTIMORE.—The city will build a filtration plant. Estimated cost, $25,000. J. W. Lee, city engineer.

Massachusetts

ASHLAND.—The United States Color & Chemical Co., 15 Custom House, Boston, will build a three story, 44 x 84 ft. research building here.

Minnesota

MOUNTAIN IRON.—The Board of Education will install a filter and purification plant for swimming pool, in connection with the 3 story, 145 x 173 ft. school which it plans to build on Main St. Total estimated cost, $200,000. H. C. Mitchell, secretary.

Mississippi

PASCAGOULA.—The City Commissioners will receive bids until Mar. 11 for the construction of sanitary and storm drainage sewers to include a sewage disposal plant. Xavier A. Kramer, Magnolia, engineer.

Missouri

ST. LOUIS.—The Floor Shine Paint & Varnish Co., 2744 Olive St., will build an addition to its factory. Estimated cost, $30,000.

Nebraska

OMAHA.—The Omaha Refining Co., Theatre Building, will build oil refinery consisting of two buildings, two stories. 24 x 80 ft. each, at East Omaha. Estimated cost, $10,000. D. W. Lennox, 460 Brandeis Theatre Building, engineer.

New Jersey

MILLTOWN.—The Elizabethtown Water Co., 68 Broad St., Elizabeth, will build a filter house and pumping station here. Estimated cost, $150,000.

NEWARK.—The Department of Streets and Public Improvements has recommended that City Council issue $250,000 bonds for the construction of a garbage disposal plant; plans include the construction of two small incinerators and a reduction plant.

PHILLIPSBURG.—The city will build a sewage purification plant. Estimated cost, $500,000. C. E. Tilton, city engineer.

New York

BROOKLYN.—The State Hospital Commission, Capitol, Albany, will receive bids until Feb. 19, for building a sewage disposal plant at the Creedmoor Division of the Brooklyn State Hospital. Estimated cost, $30,000. Noted Oct. 15.

BUFFALO.—The University of Buffalo, 24 High St., will build a chemical laboratory. About $150,000 available for same.

NEW YORK.—The Commissioner of Water Supply, Gas & Electricity, Municipal Building, received bids Feb. 5 for furnishing and delivering liquid chlorine, from the Hooker Electro Chemical Co., 40 Wall St. $7955; Arnold Hoffman Co., Inc., 55 Canal St., Providence, R. I., $8295; Electro Bleaching Gas Co., 18 East 41st St., $8395; furnishing and delivering chloride of lime, from Arnold Hoffman Co., Inc., 55 Canal St., Providence, R. I., $1095; Knickerbocker Supply Co., 147 Church St., $1437; H. Greenberg, 120 Broadway, $1554. Noted Feb. 1.

ROCHESTER.—The city will build a sewage disposal plant, in the 23rd Ward near the Rome, Watertown & Ogdensburg R.R. bridge. Estimated cost, $30,000.

POUGHKEEPSIE.—The State Hospital Commission, Capitol, Albany, will soon award the contract for improving and enlarging water system at the Hudson River State Hospital here involving the building of an intake crib in the Hudson River thence to filters, changing water main and reservoir. Estimated cost, $40,000. L. F. Pilcher, state architect. Noted Feb. 15.

UTICA.—The State Hospital Commission, Capitol, Albany, will receive bids until March 4 for the construction of a two story, 44 x 60 ft. laboratory and mortuary at the State Hospital here. Estimated cost, $50,000. Noted Jan. 15.

WATERTOWN—Knowlton Bros., 139 Mill St., will build an addition to its paper mill. Estimated cost, $50,000. C. Eaton, Sherman Building, engineer.

North Carolina

WILMINGTON.—The city has awarded the contract for building four filter unit each having a daily capacity of 400,000 gallons, to the Pittsburgh Filter Co., Farmers Bank Building, Pittsburgh, Penn. Estimated cost, $50,000.

Ohio

OBERLIN.—The Board of Education is having plans prepared by F. C. Warner, architect, 767 Hippodrome Annex, Cleveland, for the construction of a two story, 75 x 180 ft. high school building, to include chemistry, botany and agricultural laboratories, etc. Total estimated cost, $225,000.

Oklahoma

BILLINGS.—The Greater Oklahoma Oil Corporation will build a refinery having a capacity of 2000 barrels, and is in the market for tanks, pumps and stills. G. B. Shirrett, president.

Pennsylvania

ERIE.—The city will construct an intercepting sewerage system and a sewage disposal plant. Chester & Fleming, Union Bank Building, Pittsburgh, engineer.

TIDIOUTE.—The National Gasoline Co., recently organized with a capital of $200,000, will build a large refinery here.

Rhode Island

PROVIDENCE.—The Public Building Commission, City Hall, will install a chemical laboratory in the three story, 300 x 170 ft. high school building which it plans to construct on Pond St. Total estimated cost, $500,000. Hoppin & Field, 32 Westminster St., architect.

South Carolina

CHARLESTON.—The Eitwan Fertilizer Co. will rebuild its two story acid chambers on the Cooper River recently destroyed by fire. Estimated cost, $125,000. F. Burledge, president.

Texas

FORT WORTH.—The Panther City Oil & Refining Co. will build an oil refinery, having a daily capacity of 10,000 barrels. W. B. Townsend, Flatiron Building, president.

HOUSTON.—The Crown Oil Co. has awarded the contract for the construction of an oil refinery on the Houston Ship Channel, to the W. C. Hedrick Construction Co. Estimated cost, $750,000. Noted Dec. 15.

Virginia

MONEY POINT (Gilmerton P. O.)—The Hubbard Fertilizer Co., 802 Keyser Building, Baltimore, Md., has awarded the contract for the construction of a one and two story, 150 x 192 ft. fertilizer plant here, to W. J. Gregory, 501 Law Building. Estimated cost, $50,000.

NEWPORT NEWS.—The Construction Division of the War Department, Washington, D. C., will build a sewage disposal plant and septic tank at Camp Alexander, here. Estimated cost, $20,000.

West Virginia

ELKINS.—The city will install a filtration system. Address A. M. Wardle, Sanitary Branch of the State Health Department, Charleston.

Wisconsin

MENASHA.—The Lakeside Paper Co. will build an addition to its paper mill. Estimated cost, $80,000.

RICE LAKE.—Stein, Hirsch & Co., 111 West Washington St., Chicago, Ill., will build an addition to its starch factory here. Estimated cost, $200,000.

British Columbia

KASLO.—The Gibson Mining Co. will build a concentrator plant. Estimated cost $25,000. C. D. Empfield, secretary-treasurer.

VANCOUVER.—The L'Air Liquide Societe, 1 Ernest St., Montreal, Que., has awarded the contract for the construction of a two story, 75 x 85 ft. factory, on 5th and Yukon Sts., to S. J. Newitt, 954 17th St., W. Estimated cost, $25,000.

Manitoba

WINNIPEG.—The Legislation Committee of the City Council will build a pulp and paper mill to be owned by the city. Estimated cost, $3,000,000. F. O. Fowler, is interested.

Ontario

BRAMPTON.—The town will install a filtration and sterilization plant. A. E. Davis, clerk.

Quebec

CAP DE LA MADELINE.—The Riverside Lumber Co. will build a pulp mill here. Estimated cost, $200,000. H. Bierman, manager of the Canadian-Belgo Pulp & Paper Co., Shawinigan Falls, is interested.

GRAND MERE—The Laurentide Co., Ltd., McGibbon and 3rd Aves., will build a paper mill. Estimated cost, $400,000. George Cahoon, president.

Ontario

OTTAWA.—The Board of Control has applied to the City Council for authority to issue $100,000 debentures for the construction of laboratories and nurses' quarters at the Royal Ottawa Sanatorium. A. F. MacCallum, City Hall, Ottawa, engineer.

Coming Meetings and Events

THE AMERICAN ELECTRO-PLATERS' SOCIETY, NEW YORK BRANCH, will have its 10th annual hanquet at the Broadway Central Hotel, Saturday, Feb. 22, at 7:30 p. m.

THE AMERICAN INSTITUTE OF MINING ENGINEERS, which includes the Institute of Metals Division, will meet at the New York Headquarters, 29 West 39th St., Feb. 17 to 20 inclusive.

THE CANADIAN MINING INSTITUTE will hold its twenty-first annual meeting on March 5 to 7, 1919.

THE SOCIETY OF INDUSTRIAL ENGINEERS plans a national conference at New York March 18-21 at the Hotel McAlpin, at which there will be a discussion of labor by both employers and labor leaders. Internal plant organization and also the elimination of fatigue will be other leading topics.

Industrial Notes

THE NEW JERSEY ZINC CO. announces the removal of its general offices to 169 Front St., New York City.

COLGATE & CO., 72 and 74 Grand Street, Jersey City, had an explosion on Feb. 4 in its laboratory which killed two men and injured seven, due to an electric spark igniting fumes of ether. Dr. George Pierce, a chemist, who was working with chemicals used in the manufacture of toilet preparations, was one of the victims.

PASQUALE NIEKE & Co., Scoli D'Azeglic 7, Leghorn, Italy, handles the importation of machinery and tools and certain lines of chemicals, particularly nitrates, phosphates and sulphates. The company would like to establish connections with American manufacturers in these lines.

THE PORTUGUESE IMPORT & EXPORT CO., LTD., Rua dos Douradores 83, Lisbon, Portugal, would like to correspond with American firms engaged in the sale of heavy chemicals with a view to becoming representatives.

THE METAL & THERMIT CORP., New York City, announces the appointment of Mr. Arthur F. Braid as sales manager of the metal and alloy department. Mr. Braid started with this company seven years ago as a traveling salesman, but after a few years of service in that capacity he was appointed assistant superintendent of the Jersey City plant, in charge of the manufacture of carbon-free metals and alloys. When the United entered the war, he assumed active charge of the metal sales at the New York office of the company.

FACTORY PRODUCTS CORP., 2 Rector St., New York City, announces its organization for general export and import trade. It has acquired the business and goodwill of the Factory Products Export Corp. and the Manufacturers' Agents Co., Inc. The association of Bonbright & Co., Inc., will continue as financial agents for the consolidated companies. A new department for exportation of engineering supplies, machinery, hardware and building materials will be operated in association with the Engineers Corp., a subsidiary of the J. G. White Engineering Corp. of New York.

THE LIBERTY NATIONAL BANK of New York has created an industrial department for the purpose of offering advisory service on matters pertaining to manufacturing and industrial problems. The new work will be directed by Mr. Donald D. Davis, who has had practical engineering, accounting and factory executive experience.

WARREN, WEBSTER & Co., announce the opening of an office at 805 Sumpter Building, Dallas, Tex., with Mr. W. B. Irwin in charge as district representative.

BUTLER & HAYES, INC., has opened an office at 220 Devonshire St., Boston, Mass., as mechanical and chemical consultant and experimental engineer. The testing laboratories are fully equipped for the study of industrial problems.

THE AMERICAN BOSCH MAGNETO CORPORATION is the official name of the former Bosch Magneto Co., which was recently sold by the Alien Property Custodian of the United States to the highest bidder. The entire holdings and organization, including the Bosch works at Springfield, Mass., have been taken over and the large output will now be devoted entirely to the requirements of American manufacturers and the public.

THE EDISON STORAGE BATTERY CO., New York City, announces the removal of its New York sales office from 209 West 76th Street to 247-251 West 35th Street.

THE ELECTRIC STEEL CO. OF INDIANA has opened an office in the Penobscot Building, Detroit, Mich., with Mr. A. J. Kinnucan as district manager.

Manufacturers' Catalogs

THE HEINE SAFETY BOILER CO., St. Louis, Mo., has just received from the press the latest edition of "Boiler Logic," an 86-page treatise on steam boilers, with a supplement in color of a Heine boiler set over an underfeed stoker. This interesting catalog covers: I. Some fundamental considerations of boiler design; II. Practical baffling of water-tube boilers; III. Heine boilers for different fuels, firing and services; IV. Overloads; V. The boiler as a pressure vessel, and VI. Details of construction of the boilers.

THE COKAL STOKE CO., Chicago, Ill., has issued two pamphlets on its stokers.

THE STEERE ENGINEERING CO., Detroit, Michigan, calls attention to Bulletin No. 36, dealing with plant models. This 16-page booklet illustrates and describes practical methods employed in analyzing and determining the purchaser's requirements.

THE LAKEWOOD ENGINEERING CO., Cleveland, Ohio: Bulletin No. 26 pictorially describes clamshell buckets, diggers and handlers, and gives general data as to type-size, load, water level, thickness of shells, weight, diameter of sheaves, cable size recommended, amount of cable overhauled, lifting speed per minute and horse power required together with descriptions of the different types.

THE QUIGLEY FURNACE SPECIALTIES CO., New York City, calls attention to Bulletin No. 10 which treats of the air transport system for transporting and burning powdered fuel.

New Publications

THE JOURNAL OF THE AMERICAN STEEL TREATERS SOCIETY OF CHICAGO has appeared and promises to contain valuable information, particularly for steel metallurgists. Mr. A. F. MacFarland, metallurgist, U. S. Ball Bearing Mfg. Co., Chicago, is chairman of the publication committee. The Journal will appear each month and will represent the activities of the American Steel Treaters Society of Chicago. Mr. T. E. Baker, production engineer, Miehle Printing Press & Manufacturing Co. of Chicago, is president, and Mr. A. G. Henry, metallurgist, Illinois Tool Works, Chicago, is secretary-treasurer.

THE MANUFACTURER'S WAGE PROBLEM. By Herbert F. Perkins of the International Harvester Co. This pamphlet is published by the Union League Club of Chicago and can be purchased from them at 5c. per copy.

NEW U. S. GEOLOGICAL SURVEY PUBLICATIONS: I:A, The Economic Limits to Domestic Independence in Minerals. By George Otis Smith. (Mineral Resources of the U. S., 1917, Part I), published Dec. 28, 1918. I:B, International Control of Minerals. By C. K. Leith. (Mineral Resources of the U. S., 1917, Part I), published Dec. 31, 1918; I:10, Magnesium in 1917. By Ralph W. Stone. (Mineral Resources of the U. S., 1917, Part I), published Dec. 11, 1918; II:20, Peat in 1917. By C. C. Osbon. (Mineral Resources of the U. S., 1917, Part II), published Dec. 19, 1918.

NEW BUREAU OF MINES PUBLICATIONS: War Mineral Investigations Series No. 7, Review of the Manganese Situation. By C. M. Weld, dated Dec., 1918; No. 5, Production of Ferromanganese in Blast Furnaces. By P. H. Royster, prepared in co-operation with the School of Mines of the University of Minnesota, dated December, 1918; An Absorption Method for the Determination of Gasoline in Natural Gas. By W. Y. Dykema and Roy O. Neal of the Bartlesville Station of the Bureau of Mines.

THE UNITED STATES TARIFF COMMISSION has issued its second annual report for the fiscal year ended June 30, 1918. The Commission has continued its preparation of a tariff information catalog for the purpose of facilitating legislation by Congress. The Commission has published several handbooks on different industries and has a number of others in preparation. The chemical and metallurgical industries have received special attention in the commodities that have been covered thus far by the Tariff Information Catalogs.

Post-War Meetings of Scientific Societies

WE NOTE the approaching sessions of two important conventions which have special interest for chemists and electrochemists. The American Electrochemical Society will meet in New York, April 3-5, and will make a special feature of papers on subjects that were taboo during the war, but on which information has now been released. Considering electrochemistry's notable contributions to modern warfare, we may look for announcements of intense interest. In the following week, April 8-11, the American Chemical Society will meet at Buffalo and will give special consideration to needed Congressional legislation with relation to the chemical industry. Both meetings will reward attendance by members of the profession.

Validation of Informal Contracts

THERE is prospect of immediate legislation that will afford relief to those who were engaged in the production of munitions of war when armistice was declared, and who found themselves embarrassed by the non-existence of formally executed contracts with the Government. Although Government officials recognized that many of these agreements were *bona fide*, the Comptroller of the Treasury refused to recognize the obligation and the contracts were outlawed on technical grounds. Representations were immediately made to Congress, and several bills were introduced. The House and Senate passed different bills, but conferees have drafted a new bill which they will recommend for passage. According to its terms, claims must be presented before June 30, 1919. The Secretary of War will be authorized to settle obligations for war supplies, and the Secretary of the Interior will be authorized to discharge agreements, express or implied, with those producers of ores named in the so-called War Minerals Bill, the production of which was urged or demanded by Governmental agencies.

Abolish Duty-Free Imports of Chemicals

EACH succeeding National Exposition of Chemical Industries has emphasized the growing independence of our country in chemical matters, until the idea has become fairly well grounded. If the familiar German label has not become abhorrent for any other reason, its discovery on chemicals used by the enemy in gas warfare should make it an outlaw in respectable laboratories. We have only ourselves to blame, however, for the inculcation of the idea that Germany alone could supply our laboratory needs, and particularly those of

our schools, colleges and universities. By Congressional legislation we have permitted educational and similar institutions to import chemicals and apparatus duty-free, until the number of such availing themselves of this privilege in 1914 was probably in the neighborhood of 10,000! Imports of this class were valued at $572,726 in the fiscal year 1913, and at $704,496 in 1914. We believe we voice the patriotic sentiment of every educational institution when we say that Congress should repeal that clause of the tariff which permits the duty-free importation of chemicals and apparatus, and thus encourage American industry in its willing efforts to meet our own needs. It may cost more money for a time, but the additional expense will be welcome and we can find solace in the knowledge that we can shortly build up a million-dollar industry where little or nothing existed before. American manufacturers have shown their ability and their readiness immediately to supply our schools with American products. American teachers undoubtedly are ready and willing to patronize them. It remains only for Congress to act, and that should be done speedily before German agents begin to reconstruct their lost markets.

Favorable Prospect for Water-Power Legislation

AT THE hour of going to press advices from Washington announce the agreement of House and Senate conferees on provisions for water-power legislation. It is expected that a report will be made to both bodies on or before March 1, and unless there is a filibuster against the bill there is every prospect that it will be passed. The principal provisions do not differ greatly from those previously reported in CHEMICAL & METALLURGICAL ENGINEERING. The control of water-power development is vested in a committee of the Secretaries of the Interior, War and Agriculture. The definition of net investment with relation to recapture of water-power projects by the Government at the end of a fifty-year license period remains practically unaltered. If we are so fortunate as to secure a water-power bill from this session of Congress it will constitute one of the most important steps that could be taken toward reconstruction along sound and substantial lines.

Progress in Zinc Smelting Awaits Impulse From Metallurgists

EVERY zinc metallurgist, worthy of the name, has schemes similar to those of Mr. CHOATE presented elsewhere in this issue, and can hardly wait for the opportune moment when some of the more apparent drawbacks to the present industry can be replaced by more efficient and more modern methods. However, they are almost invariably entirely occupied in keeping the existing plants going, and therefore most of the plans unfortunately remain "dreams."

Mr. CHOATE'S many proposals are worthy of careful consideration and free discussion, but the best results would necessitate the disclosure of practical experiences from a very large number of zinc metallurgists. Such a discussion would be of enormous value indeed! Obvious impediments have so far stood in the way. Thus, in practically all companies the capital is represented by non-technical men who veto the exchange of confidences between the technical staffs. These directors have not yet realized that their mistaken secretiveness excludes ten new ideas from their organization for each quasi-trade secret impounded, while on the other hand the "open door" has done much to advance such as the Phelps-Dodge Corporation to the forefront of copper smelting. Granted that the first duty of the individual operators is to their respective employers, still they can take the first move toward turning the zinc industry from the approaching cul de sac by continually bombarding the management with the idea that at the very worst an interchange of ideas could not make the situation any more difficult.

Advance in zinc smelting has been slow not because the metallurgists have been unwilling or unable to improve the practice—a frequent reproach—but because the large appropriations necessary for experimentation have been denied them. Zinc plants are still built in comparatively small units, the tonnage treated is greatly inferior to that of smelters producing the other common metals, and large capital investments have ordinarily been absent. The one exception to this rule is the Anaconda Copper Mining Co., which by unstinted expenditure of funds and talent accomplished very excellent results along an entirely new and most difficult line of metallurgy, namely, by the electrolysis of sulphate solution. Under similar circumstances others in the profession could no doubt accomplish similar results, and along different lines.

Every one feels the pressing need; the favorable moment has arrived; metallurgists should embrace it to force, if need be, halting recognition of their latent capabilities.

Hard Times For Inventors

THE INCOME tax certainly does pinch a fat pocketbook! It is a fashion of the day, and there is no use protesting; but its probably constitutional, although approximately confiscatory, features in relation to large incomes are likely to slow down the machinery of industrial progress. Every new idea must pass through a speculative phase before it becomes established. The man of limited income cannot afford to speculate. The consensus of human experience is against it. If he has a little something set aside for a rainy day or to provide for old age, he should not play fast and loose with it. With all our reforms and changes in public policy we have not yet reached the point at which we discourage thrift.

Rich men can afford to speculate. They set aside what they are willing to lose, and "take fliers" with it. It is by means of such excess wealth that most new enterprises have been started, and these make for competition, as well as for industrial progress, while they bring down prices in the end. We are not praising rich men, or making any plea for an increase in millionaires; we are merely stating the fact that new enterprises are usually started by savings of the well-to-do; by means of funds that are or should be available for speculation.

Corporations may speculate on new methods, processes and materials within reason. The means for this is taken from research funds. But corporations are slow to change factory practice, and we could fill all our pages with testimonials taken from inventors of

the day to prove that novelties and improvements are hard to get through the front door of industry. It is generally admitted to be wholly useless to offer patents of any kind to certain corporations. We are not complaining; we are merely recording the experiences of the past. As instances of the difficulty of getting even great inventions over the speculative stage we may mention HALL with his aluminium process, or HERMAN FRASCH'S conquest of the sulphur problem in the Gulf States. We should probably still be without sulphur if it had not been for H. McK. TWOMBLY, MRS. HEWITT, and a few others who took a flier on backing the Frasch process.

Banks are not allowed to speculate, but banking institutions by their affiliations with persons of wealth can offer them the opportunity to speculate of their own free will. That is the way in which great promotions have been effected. It comes right back to the rich men again.

Although hope may spring eternal in the human breast, few of us like a treadmill. The incentive to make money only to see it taken away again by taxation is, somehow, not very strong. Possibly it should be great and patriotic, but it is not so regarded. Nobody goes up to the tax-collector's office joyfully and with a brass band. The whole proceeding has never yet acquired charm. Therefore rich men are growing wary of taking fliers in new enterprises, on the ground that, if they lose, their money will be gone, and if they win their profits will be taken away by taxes. They are less inclined toward new things that look good. And the inventor is having a hard time of it.

Iron and Steel Production in 1917

APART from the pig iron and steel rail statistics for 1917, the industry's production statistics for that year are belated and have appeared only in the past fortnight, the delay, of course, being due to the fact that there was more important work on hand, by way of winning the war. Despite their age the figures are quite interesting.

The total production of steel ingots in 1917 was 43,619,200 gross tons, in close keeping with estimates already made and comparing with 41,401,917 tons in 1916, previously the record year. Production in 1906 was 22,624,431 tons, or more than 3,000,000 tons in excess of the best previous output, so that production almost doubled in eleven years. There was more than a doubling from 1905 to 1916.

The production of steel castings in 1917 was 1,441,407 tons, showing an increase of 5 per cent over 1916, previously the record year. From 1906 to 1917 the production of steel castings practically doubled, yet that was really no remarkable record, considering the enormous field of iron castings from which the steel casting could draw if, as some of its votaries used to think, it was going to displace the iron casting in so many uses. Beyond question the steel casting serves an extremely useful purpose in many connections, but the uses do not run into tonnage to the extent that is expected by many.

What is commonly called for statistical purposes "the production of steel" was 45,060,607 tons in 1917, that being the sum of the production of steel ingots and of steel castings. So far as its weight goes, the steel casting is very nearly a finished product, but it is not so with the steel ingot. That is merely a form of material which for intelligent and economical operation of works it is necessary to weigh. Ingots are not an article of commerce to any extent, even between works. There is a large reduction in weight from the ingot to the finished rolled steel, due to the production of scale and of scrap, materials that are reclaimed, the one by the blast furnace, the other by the open-hearth furnace.

The production of finished rolled steel, on the other hand, represents substantially commercial steel, material that is bought and sold and put into use, with relatively little loss of weight. The statistics of rolled steel measure the material after its last hot rolling and after the necessary shearing. Thus sheet bars are not reported as rolled steel, the rolled material reported being black sheets, black plates for tinning and tin mill specialties. Pipe, on the other hand, is reported separately, while the skelp in included as finished rolled steel. Rods, again, are reported rather than billets or drawn wire.

The production of finished rolled steel in 1917 was 31,199,943 gross tons, against 32,380,389 tons in 1916. The rolled steel for 1917 plus the steel castings makes a total of 32,600,000 gross tons, which in a commercial sense might be considered the product of the steel industry, with some allowances for loss in wire drawing, pipe making, etc.

During the major portion of 1917 the United States was in the war and quite actively in it so far as preparation was concerned, while the industry was supplying much material for the Allies. Nevertheless, the analysis of total output of rolled steel, as rails, rods, plates, hoops, etc., diverged but little from the usual or normal distribution. Taking rolled iron and steel together, there having been 1,867,757 tons of iron rolled, there was a total of 33,067,700 tons. Of this, 3,110,000 tons was structural shapes, about the normal proportion, while 2,944,161 tons was rails, also not much out of line. The exceptionally heavy production of wire rods in 1916, however, was not repeated, wire rod production dropping from 3,518,746 tons in 1916 to 3,137,138 tons in 1917.

It may seem a trifle strange to those not addicted to statistics that there should be a larger tonnage of wire rods produced than of rails, but this has been the case for several years. Wire is ubiquitous, like the tin can, and indeed there was 1,512,146 tons of tin and terne plate made in 1917, or more than half the rail tonnage. The weight of steel in a mile of track laid in 100-pound rails is about equal to the weight of tin plate required to make 1,400,000 two-pound tin cans, but the tin can is more an article of individual consumption, and thus is necessarily very numerous.

An interesting item is that the production of sheared plates, ¼-inch and heavier, increased from 1,865,642 gross tons in 1916 to 2,461,938 tons in 1917, a gain of 596,296 tons. This was due to harder driving rather than to increased capacity, as most of the large plate mills lately built did not come in until 1918 and some of them indeed contributed but little even to that year's production.

Readers' Views and Comments

The Present Status of Oil Shales

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 25 of your Jan. 1 issue you publish an article headed "The Present Status of Oil Shales." Therein you say, "while the Scottish shale industry exists by virtue of the ammonia recovered as a by-product." Some years ago this statement would have been a true representation of the case, but it is true no longer, and your making it now may be the cause of much waste of capital. You use this statement as the basis of an argument, by which you endeavor to encourage the adoption in the States of what is known as the Scotch retort, but which I, in order that no misunderstanding may arise, have renamed the Scotch dual purpose retort.

I fear your study of the history of the oil shale industry in Scotland and of the evolution of the retort in Scotland and elsewhere has not been as thorough and complete as is desirable. The designing and construction of the Scotch dual purpose retort were the result of certain local conditions that have since very largely ceased to exist in Scotland, and which do not exist in any other locality where oil shales are found. The dual purpose retort was the result of these conditions, and credit is due the Scotch operators for perfecting the retort to suit the conditions they had then to meet. But for countries or for localities where those conditions are not present it would not be wise to advise the adoption of such an expensive retort, knowing that more expense would have to be incurred to adapt it to the local conditions existent.

Before any one gives advice, before any one decides what retort to operate, it would be well to understand what were the special conditions that evolved the Scotch dual purpose retort. The conditions were as follows: The sale price of crude oil was very low, away under to-day's prices and under the prices that existed immediately before the war. The sale price of sulphate of ammonia was very high, much higher than the price immediately before the war, or than the price will be in the future (see article in your journal of Dec. 15, page 827). The cost of manufacturing the sulphate of ammonia was very low, lower than it is to-day or than it will be in the future, with the exception possibly of a few localities. The shale to be retorted was low in yield of oil, but relatively high in yield of nitrogen. Money and machinery were low in cost.

What are the local conditions in the U. S. and in Canada? The sale price of oil is high, while the sale price of sulphate of ammonia will be very low, yet the cost of manufacturing the latter will generally be very high. The shale to be retorted is comparatively high in oil, but in the States generally low in nitrogen, while in Canada the nitrogen contents are sometimes very high, although deposits are found where the nitrogen contents are low. Money is dearer than in Scotland, and machinery, when erected, will cost much more. In fact nearly every condition to be faced on this continent is different from the conditions that existed in Scotland and which were responsible for the construction of the Scotch dual purpose retort.

Broadly, it may be claimed that while local conditions in Scotland at that time made the recovery of the nitrogen desirable, the local conditions existing in the States and Canada will make the recovery of the nitrogen generally unremunerative. This being the case, how can you or any one occupying a neutral position recommend or advocate the construction of the Scotch dual purpose retort, costly to construct and complicated to operate, a retort that costs more than double the price of the single purpose retort, while the accessories cost treble, upon all of which extra expenditures of capital there is likely to be no financial return?

The Scotch dual purpose retort is by no means a simple retort to operate, and if not carefully operated is liable to become damaged, entailing considerable loss of time and heavy expenditures for repairs. The requirements of the nitrogen-recovery half of the retort fight against the requirements of the oil-recovery half. The operator is ever "between the devil and the deep sea." If the heat is allowed to become lowered in the nitrogen-recovery half, the recovery of nitrogen is reduced; if the heat is kept up to the required temperature for good nitrogen recovery, the oil returns are reduced, and an excess of gas is produced. Owing to the constant variations in quality observed in all shale beds, or for other reasons, it is impossible so to construct the dual purpose retort that the requirements of the parts will never disagree.

Years ago was not the world told, "No man can serve two masters"? In the Scotch dual purpose retort this is what the operators have been trying to accomplish. That the efforts proved remunerative in Scotland, under the peculiar and special conditions then and there existing, is no justification for your advocacy of the adoption of this kind of retort, under conditions entirely different. Had you studied the history of the Scotch dual purpose retort, you would have learned that that retort has not been uniformly successful in its operation. You would have learned that when used for retorting shales of a quality different from that found in Scotland it proved a most disastrous failure. Did you never hear of the enormous amount of money lost in Australia through the failure of these dual purpose retorts? More money was lost than would have paid for all the experimental and "freak" retorts produced in the States and "then some," the construction of which is so deplored by Mr. Day.

I have a world of respect for Mr. David T. Day as a chemist, and also for the good work done by him on the oil shales of the United States, but this is not so much a problem for a chemist as for a business man with experience in operating chemical processes, and as such I have no hesitation in stating that the dual purpose retort, whether Scotch or American constructed, is not the retort required to-day to retort the majority of the shale found on this continent.

One of the experimental retorts mentioned by you is

the Wallace. Methinks I have read words of great commendation of this retort, made over the signature of David T. Day. Although I object to the intermittent method used of supplying the shale and of unloading the spent shale, especially when the shales being retorted are lean, I recognize that, if it be demonstrated by commercial operation that the oil contents of shale can be removed with only one hour of exposure to heat, this retort will cause a revolution in the designing and construction of retorts, a revolution that will give a black eye to all dual purpose retorts, be they Scotch or otherwise.

The retorting of shale will have to be considered on its own individual merits, that is, the retort and the working of the retort will have to be adapted to the quality of the shale to be retorted, and always with due regard to local climatic, industrial, financial and commercial conditions, the one aim being to secure for the men providing the money required for construction and operation the largest possible return upon their investment.

LOUIS SIMPSON.

Instituto Cientifico Industrial del Salitre de Chile

To the Editor of Chemical & Metallurgical Engineering

Sir:—I am enclosing a copy of a circular letter which was distributed throughout Chile and resulted in the formation of the "Instituto Cientifico Industrial del Salitre de Chile." The idea has awakened very general interest in nitrate and allied circles which augurs well for the success of the project.

Knowing the general interest which is taken in Chilean nitrate in the United States, I think it might be useful to make public the knowledge of the awakening of the Chilean nitrate industry.

We shall be pleased to receive subscribers from the United States and hope that the steps taken here may find support among the scientific and technical societies of the United States in the many directions in which one society can assist another, and we trust that the interest which nitrate has aroused during the past years will lead to much research work in the U. S. A. which may help in one way and another to clear up many of the difficulties which beset the workers and the industry here.

BELISARIO DIAZ OSSA.

Santiago de Chile.

TRANSLATION OF SPANISH CIRCULAR LETTER

SANTIAGO, Oct. 12, 1918.

DEAR SIR:—The undersigned have the honor of inviting you to a meeting, which will take place on the 18th inst. at 2.30 in the rooms of the Sociedad de Fomento Fabril, Moneda 759, and which has for its object the formation of a scientific and industrial society in connection with the nitrate industry. You will deeply appreciate the advantages which such a society will confer not only on the country itself in its educational sense but also on the nitrate industry and those who are engaged in the study or direction of its different phases.

It is characteristic of the present period that there is a marked tendency to co-ordinate not only science and industry but also the workers who are occupied in the various branches of such scienece and industry, and there is little doubt that all those actually engaged in the various branches of the nitrate industry, in the technical studies relating to the process in use or in projection, or the actual manufacture and commerce of nitrate of soda will find, in a society of this kind, a new field for their activities, a place in which they can expound their ideas and discuss with their co-workers the different phases of the problems which are presented continually. Societies of this class, which aim at the reunion of men of science and of commerce, exist in almost all countries and for almost all industries, many of these latter being of less importance and of less vital interest than is the nitrate industry for this country.

The war has demonstrated the absolute indispensability of this class of society for the harmonious development of all industries. Governments have endeavored, even by compulsion, to form them where previously they did not exist, and have stimulated existing ones by the esteem with which they have regarded their activities. As an example, it will suffice to cite the case of France, where, in order to give the greatest development to French industries, both chemical and allied, the "Societé de Chimie Industrielle" was founded in 1917, whose valuable work is now beginning to make itself evident.

There exists in this country sufficient of the necessary elements for the formation of a similar technico-industrial society, but at the present time these factors are disunited and dispersed, and even without knowledge of one another, and our idea is to unite these for the general good and for the good of the industry and themselves.

One of the most important activities of the society will be the publication of a "Review" in which will appear not only original contributions on work done or being done of scientific as well as of commercial and technical interest, but criticisms of such contributions, discussions and abstracts of all work done in other countries in analogous industries, patents as well as original research.

This will bring about the necessary co-operation of the technical, scientific and commercial efforts which are being made individually to-day, and will form, at the same time, a bond of union between the nitrate industry and the chemical industry of other countries greatly to be desired.

We trust that this idea will meet with your views, and that you will lend us your assistance in bringing this society into useful existence.

J. BERKWOOD HOBSBAWN,
BELISARIO DIAZ OSSA,
J. L. GRIGIONI.

Classifying the Perkin Medalists

To the Editor of Chemical & Metallurgical Engineering

SIR:—If industrial chemistry is divided into the branches shown in the following table, the Perkin Medalists are distributed, according to their work, thus:

		Engineering Chemistry	Industrial Inorganic Chemistry	Metallurgical Chemistry	Industrial Organic Chemistry	Industrial Electro-Chemistry	Industrial Chemical Processes
1	1906				*Perkin*		
2	1908		Herreshoff			Herreshoff	*Herreshoff*
3	1909				*Behr*		
4	1910		Acheson			*Acheson*	
5	1911			Hall		*Hall*	
6	1912		*Frasch*		Frasch		
7	1913			*Gayley*			
8	1914				*Hyatt*		
9	1915					*Weston*	
10	1916				*Baekeland*	Baekeland	
11	1917				*Twitchell*		
12	1918			*Rossi*			
13	1919						*Cottrell*
Total		None	1	2	5	3	2
Worthy of mention, in addition		None	2	1	1	2	None

There is such inspiration in the record of these men that I should like to see a memorial volume published in which their lives and works would be available. The presentation proceedings might possibly form a starting point. To me this award is an outstanding thing in industrial chemistry today in the United States.

R. K. STRONG.

Oregon State Agricultural College,
Corvallis, Oregon.

Western Chemical and Metallurgical Field

Electric Pig Iron For British Columbia

STANSFIELD'S recently issued report on electric smelting of the iron ores of British Columbia is not a particularly encouraging document for the proponents of a west-coast iron industry. The author has been assured by competent engineers that accessible power could be developed for $10 per horsepower-year, but the present available surplus from the British Columbia Electric Railway Co. would cost $27.80! It may also be safely assumed that there is available an adequate supply of magnetite (50 to 55 per cent iron). Still, considering the fact that the entire consumption of pig iron in British Columbia is but 10 tons daily, while a plant large enough to give a moderate overhead would produce five times as much, the chance of marketing the output seems rather dubious. In the light of the recent experience of our own Western electro-alloy plants, the suggestion that ferromanganese, ferrochromium and ferrosilicon be produced when the demand for pig was slack does not strike a particularly responsive chord when considered as a means to increase the operating profit of the concern. Low-silicon pig for steel conversion could be made at any time, but its local utilization would require a highly specialized plant whose economical operation on such low tonnages is more than doubtful.

Electric shaft furnaces have been producing high-grade white iron in Sweden for many years, and this type is recommended for a permanent plant. For a cheaper, temporary installation the Electro-Metals pit furnace would probably suffice, Dr. Stansfield noting that the normal product could be made suitable for gray-iron castings by the addition of ferrosilicon. Magnetite low in copper, phosphorus and titanium is thought to be procurable, by water transport, at about $4 per ton. Magnetic concentration is mentioned as a possible method of increasing the tenor of the ore charge. Charcoal would be the reducing agent, obtained from the large quantities of mill-waste now available in the lumbering industry. By-products from Douglas fir are not sufficiently valuable to affect the production costs materially, but Dr. Stansfield thinks that by charring in large kilns, the labor charges may be reduced to a point where the coal can be laid down at about $6 per ton.

Summarizing, the cost per long ton of foundry iron is estimated as follows:

Iron ore, 2 net tons at $4	$ 8.00
Electric power, 0.45 hp.-yr. at $15	6.75
Charcoal, 0.4 net tons at $8	3.20
Electrodes, 15 lb. at 8c.	1.20
Repairs and maintenance	1.00
Labor	4.50
Management	2.00
Interest, 6 per cent on total capital, and depreciation, 10 per cent on cost of plant	2.60
Royalty to Electro-Metals Co.	0.50
Total	$29.75

At this price, electric furnace pig would be on a par with imported blast furnace pig, under the present tariff of about $5. A local iron and steel plant, using coke blast furnaces, is not to be expected for a number of years; eventually blast furnace pig will command the market, but electric furnace iron should always rule the market for high-grade material.

The final recommendations are:

(a) To develop one or more of the best iron ore deposits and to make complete tests of the ore.

(b) To reserve a suitable water power for future development.

(c) To establish a plant for the economic production of charcoal from mill waste.

(d) To investigate the new process of Trood and Darrah for the production of electric pig iron, and if this is found satisfactory to begin immediately to produce the pig iron, purchasing power for this purpose until the water power can be developed.

Collapse of Kelp Potash

A highly unsatisfactory situation has been suddenly brought about with respect to the Coast potash and kelp industry—particularly disappointing to those who were in hopes that the kelp industry could be perpetuated. Briefly, the armistice and its attendant events have caused the plants to close. There are still some exceptions, but apparently their operators have in mind the cessation of operations at an early date.

It has been evident for quite a while that the closing of some of the plants could hardly be postponed to the end of the war, since these were being operated by people not possessed of the requisite skill and experience to run a chemical factory. Some of the minor plants were started ill-advisedly, and even as "wildcats," and were later taken over by other people in order to save their investment. Under these circumstances it was scarcely to be expected that any great success as pioneers would follow their efforts. Their poor extraction of potash by crude and simple methods contrasted strongly against the very profitable manner in which this was done by others working under the same conditions, and they could scarcely be expected to produce the more refined products which kelp will yield and which must be depended upon to pay the way despite cheap potash.

The Hercules Powder Co.'s plant at San Diego,[1] the largest kelp concern in existence, ceased operations because its products were principally those which enter the war industries (all of which tumbled in price the moment the war terminated). Its potash, being a very high-grade chloride, was utilized in the preparation of potassium nitrate. Its acetone, of course, went into the manufacture of munitions. Prominent among other products were various aëroplane dopes. Other things it was manufacturing, such as acetic anhydride, the rare esters, and alginate bodies, while of importance and very great promise, were not sufficient to take the place of the decreased value of the other products. Had its operations continued for another year or two, this plant would have taken its place among the most important chemical factories in the country. But, of course, throughout the war period the greatest efforts were devoted to the production of war materials, the other researches being somewhat incidental and not carried far enough to permit the continuation of operations. The company had re-

[1]See METALLURGICAL & CHEMICAL ENGINEERING, Vol. 18, No. 11, p. 576.

cently inaugurated an advertising campaign to bring these various interesting and rare substances to the attention of the chemical public, but this had not gone far enough to yield results. Its scientific staff had done work which constitutes one of the most interesting chapters in American chemistry. Fortunately the data secured there are not going to be lost, but it is a misfortune that the promising young industry represented by the fermentation of kelp could not be added to our permanent national assets.

The Diamond Match Co. has caused its plant to be dismantled. Very little is known concerning the success of its operations, but evidently the management is confident it will now be able to obtain its requirements cheaper than it can produce them from kelp. This plant produced no by-products and did not get a quantitative extraction of potash from its rather expensive process.

It seems well accepted that it is not possible to produce potash from kelp commercially in normal times by any of the means so far tried, where no by-products are recovered. This statement possibly covers the reasons for the closing of the Lorned Manufacturing Co.'s plant at Summerland (whose operations were described in CHEMICAL & METALLURGICAL ENGINEERING for Sept. 26, 1918; Vol. 19, p. 450) and the Pacific Products Co. at Long Beach. These concerns have taken the position that the best time to close their plants is promptly upon the termination of a period of profitable operation and not to postpone it to a time when, through a sudden fall in the market price of potash or some accident to their plant, losses might be incurred which could not be recouped. This is entirely logical.

At Long Beach the Sea Products Co. still continues. This plant invested but a small original capital, and its profits by conservative and fortunate management have been great. It has paid for itself several times, and so its directors feel that they are justified in prolonging its operations. The Swift Fertilizer Co. at San Diego is still operating, and possibly will continue. Its plant has been a satisfactory potash producer, and it will possibly produce valuable by-products somewhat later.

Unfortunately, the experiments made at the Department of Agriculture's plant at Summerland have not been carried to that point where the Government's agents can say to the managers of the producing plants just what their costs and returns would be for the various by-products established as procurable and which offer definite promise of profitable extraction. Furthermore, to produce these substances would require a quantity of additional apparatus which would possibly double their present investment, and which of course they could hardly be expected to incur without a definite view of its ultimate recapture.

Gold Miners Present Program

Black Hills Mining Men's Association met at Deadwood, South Dakota, on Jan. 10, for a thorough discussion of the situation which confronts the gold producer in that district as well as in other parts of the world. Recognizing the real need of more gold, the continuing high cost of labor, machinery and supplies, the decreasing grade of ore in operating properties and the decadence of prospecting, the association passed resolutions prepared by H. W. SEAMAN, asking their State Legislature to memorialize Congress for relief along the following lines:

1. Remove restrictions upon the sale of bullion in domestic and foreign markets.
2. Allow liberal figures for plant depreciation and mine exhaustion.
3. Remove or refund special war taxes.
4. Exercise pressure toward more reasonable prices for machinery and supplies.
5. Extend aid to all endeavors to produce *new* gold.

Chloridizing Volatilization of Complex Ores

Metallic volatilization in complex ores in 100-lb. lots has been under experimentation for the past six months at the co-operative laboratory maintained by the Bureau of Mines and the University of Utah. A small-sized but rugged rotary kiln, 20 ft. long and 13 in. clear inside diameter is heated by oil burners. Ore is broken to 16 mesh, mixed with a proper amount of calcium or sodium chlorides, and fed to the upper or cool end of the kiln. Rotation of the furnace gradually works the mixture through, emerging approximately at 750 deg. C., this temperature varying somewhat for different ores. Seemingly oxides, carbonates and silicates of silver, gold, lead and copper are driven off as chlorides by this treatment, volatilization on silver ordinarily amounts to 75 per cent or better, while less than 10 per cent of the gold, lead and copper with all of the zinc remains in the residue. In furnacing, the coarser kernels of ore retain their original shape, while the fines roll up into small friable balls.

Fumes from the kiln are sucked through appropriate dust chambers by a fan, and then delivered to a Cottrell precipitator. Practically all of the coarser dust and considerable fume are collected in the chambers, while much of the finer fume is caught by electricity—an additional Cottrell treater is contemplated in order to better the final recovery. A certain degree of humidification may be necessary before complete clearance is effected, however. Dust and fume are melted with a limestone flux; by this means the metallic chlorides are reduced to metal, with the formation of a calcium-chloride slag, which, of course, may be pulverized and reused as a volatilizing reagent.

THOMAS VARLEY is the metallurgist now in charge of the station, although this experimentation has been in course of development for a long time under the personal direction of R. H. BRADFORD, professor of metallurgy at the university.

Passing of Goldfield Consolidated Mines Co.

After having produced in excess of $70,000,000 and paying dividends in excess of $28,000,000, Goldfield Consolidated Mines Co. has, within the last two years, extended its leasing policy until the small amount of remaining ground does not justify maintaining the staff and machinery necessary for its administration. A 5-yr. lease has therefore been given on the entire mining property, mill excepted, to an independent Goldfield Development Co. on a basis of royalty on ore produced, equaling 15 to 20 per cent of the proceeds from its sale, after deducting marketing charges.

New York Meeting of the American Institute of Mining Engineers

Annual Meeting Is Marked by Large Attendance and Excellent Program—Joint Sessions Held With Canadian Mining Institute—Special Attention Given to Industrial Relations—Change of Name and Election of Officers

THE first post-war meeting of the American Institute of Mining Engineers, held in New York City Feb. 17-20, showed in its attendance and general atmosphere the freedom and removal of restraint which the end of hostilities has brought to the engineering profession. There was a generous sprinkling of military uniforms at the various gatherings, worn by engineers who have not yet been mustered out of the service; but for the most part those members of the profession who had been giving so much of their time to war work had been relieved from public duties and were enjoying this opportunity for professional intercourse. More than 700 men registered during the meeting, giving the largest registration in the history of the Institute. The annual banquet was attended by more than 400, and all the technical sessions were well patronized by interested audiences.

Institute Changes Name and Elects Officers

At the annual business meeting it was announced that the proposed amendment to the constitution, changing the name of the Institute, had been carried, and that the name henceforth would be American Institute of Mining and Metallurgical Engineers. This alteration has been proposed for some time past in order to give recognition to the large membership of metallurgists in the organization. It is hoped also that the change will induce many more to join whose interests are primarily metallurgical rather than mining. This is particularly true of metallurgists engaged in the production of iron and steel.

Horace V. Winchell of Minneapolis was elected president for the ensuing year. Other officers elected were: Vice-presidents, Edwin Ludlow, A. R. Ledoux; directors, J. V. W. Reynders, George D. Barron, Charles F. Rand, Louis S. Cates, Stanley A. Easton.

In his annual report the secretary showed that the Institute membership increased by 666 during the year 1918, giving a total of 7158 on Dec. 31, 1918. The financial condition of the Institute is excellent, as shown by the audited treasurer's report of $8258 on hand.

Participation by Canadian Mining Institute

Tuesday, Feb. 18, was designated Canadian Mining Institute day, and was marked by joint discussions on the subjects of mine taxation, industrial relations, democracy and education, and uniform mining law for North America. President Dowling, Secretary Lamb and a delegation of members of the C. M. I. were in attendance and contributed to the discussions. The greatest interest attached to the paper on "Industry, Democracy and Education" delivered by Mr. C. V. Corless, director and manager of the Mond Nickel Co. His address was brilliant, forceful, logical and filled with choice epigrams. Based on the highest idealism, it nevertheless carried the greatest conviction, due to the earnestness of the speaker and the evident practicality of his ideas. Mr. Corless began his address with an inquiry into the causes underlying the unrest which exists throughout the world, and showed that they were not new, but were such as humanity had rebelled against for ages past—autocratic rule, not only political but

industrial as well. The prime cause of the great war he found in a conscious effort to perpetuate autocracy in political affairs. Similarly the cause of unrest in industry is not primarily low wages, long hours, no vacations and few holidays, but its essence is the individual's lack of interest in the end product of his toil. Having no chance to display his intelligence or imagination, he rebels against an external authority which he does not share.

Mr. Corless declared that political democracy and industrial autocracy cannot exist side by side, and stated that the great need of the world is democratic freedom and self-government in industry. The latter will be accomplished only by lifting the industrial problem out of the mire of sordid and selfish commercialism, and considering it from the enlightened viewpoint of right and justice in human relations. Slavery has been abolished as a political institution, and autocratic rule in industry must follow it to the scrap heap.

The Whitley scheme of industrial representation which is being tried in England met with Mr. Corless' approval as a large and necessary step forward toward industrial peace. "It is necessary to saturate our minds with the idea that the democratization of industry is fundamentally necessary," he said. Our industrial organizations have been turning out two products, one material and the other human, and we have been neglecting the latter to the point where it leaves the factory in worse condition than it entered. As a fundamental prerequisite to social democracy, Mr. Corless stated that the people must be educated to think economically, ethically and socially. We are at the beginning of a great transition period in industry, coincident with the end of the autocracy of capital. A new form of society cannot be created by changes in a political constitution, but it must find its inception in a quickening of the minds of the people in matters of justice and right. The discussion of those topics which were the subject of joint consideration in New York will be continued at the meetings of the Canadian Mining Institute in Montreal, March 5-7, 1919.

HORACE V. WINCHELL

Memorial Services

The life and work of Dr. Rossiter Worthington Raymond, past president, honorary member and secretary emeritus, were the subject of a memorial service during the session. Dr. Henry F. Drinker, president of Lehigh University, and Mr. T. A. Rickard, editor of the *Mining & Scientific Press*, spoke on the personal and professional attributes and attainments of Dr. Raymond. Both had enjoyed a long acquaintance and friendship with him and were able to speak appropriately. The Institute plans to issue a memorial volume containing tributes to the life and work of Dr. Raymond, as well as a history of the Institute which he had begun but not finished.

Services in memory of Institute members who lost their lives in the military service of their country were conducted by President Jennings. The Institute had about 845 members in the service, of whom, so far as is known, about 25 have died.

Social Features of the Meeting

The committee on arrangements promoted sociability among the visitors by various means. The noon luncheons served at headquarters were most effective in bringing together the members for a social hour. The smoker on Monday evening, with Mr. E. P. Mathewson as ringmaster, was a success from every point of view, contributing not only entertainment but also instruction. A new development in moving pictures was shown, by which it is possible to illustrate the internal action of mechanical devices, such as gas engines, machine drills, etc. Pictures on this order were used extensively during the war for the instruction of recruits, and should be quite as effective for industrial purposes. There was a large attendance of ladies at the meeting, and suitable entertainment was provided for them. Visits to Senator Clark's galleries, a theater party and trips to various points of interest in New York were arranged. The ladies also attended the noon luncheons at headquarters, and the lecture by Lieut. Pat O'Brien, who told of his capture and escape from Germany. About 350 members and guests of the Institute visited the shipyards of the Federal Shipbuilding Co., Kearny, N. J., to inspect the methods of fabricating steel ships. This company was organized by the U. S. Steel Corporation to assist the Government in its war program, but is now turning out ships for merchant trade. The yard has 12 ways and a fitting-out basin accommodating eight ships at once. The ships are 410 ft. long, 55 ft. beam and 27 ft. draft, with a cargo carrying capacity of 9600 tons. The visitors were shown through the shops and one of the ships, after which the company served luncheon at one of the dining rooms on the grounds. During the early part of 1918 experiments were under way at this yard for electric welding, with a view to building ships without rivets, but the sudden termination of hostilities brought the plans to an end.

Sessions on Industrial Organization

Two sessions were devoted to the problems of health, sanitation, housing, education, methods of employment, mental tests, Americanization, etc. Methods of employment of labor and the new change in industrial relations were discussed by Mr. H. M. Wilson, who said that the experience and knowledge of engineers impose on them the imperative duty of participating in the

solution of labor and capital problems. In the latter he saw four factors—labor, capital, the community and the managers. Most disagreements, he believed, resulted from the fact that both the employer and the employed were too engrossed in their own personal problems to sense each other's side of the question. In the Rockefeller plan of industrial representation and conference between managers and laborers, Mr. Wilson thought that a fair solution of the problem had been found. He also approved the Whitley scheme of the British.

The Use of Cripples in Industry was outlined by MR. JAMES P. MUNROE of the Federal Board for Vocational Training, which is assisting discharged soldiers who are handicapped by injury or disease. Through compensation by the War Risk Insurance Bureau and training by the Federal Board for Vocational Training, the discharged soldier is prepared for industry and is not allowed to remain a "cripple" in the old meaning of that term. This war work has shown the possibilities of retraining those who are disabled in industrial pursuits, and brings to the Federal Board a larger problem than it has in connection with disabled soldiers. Twenty thousand of the latter are to be retrained for industrial pursuits, but a larger number than this must be handled as a result of accident and carelessness in industry. In addition to this work the Federal Board has taken over the training of employment managers, begun by the War Industries Board, and plans also to give short courses in safety, etc., in schools where vocational training is being given.

Mental Factors in Industrial Organization and the part they play in labor problems were presented by MR. THOMAS T. READ. "The first requisites of success in industrial organization . . . are unity of purpose and co-ordinated activity." Failure to secure these requisites is caused in part by lack of opportunity for self-expression by the laborer in our modern industrial systems; in part by mental abnormalities in the individual which result in breaking down unity and co-ordination.

Mental Tests in Industry, the subject of one of the most interesting papers on the program, was dealt with by MR. ROBERT M. YERKES. The author gave a review of the mental tests adopted by the Army for grading enlisted men and officers as to intelligence, and showed that the gradings thus obtained were supported by classifications made later from everyday experience. He thought that these tests or similar ones should be of value in selecting men for industrial pursuits instead of leaving the choice to cut-and-try methods. The tests were prepared by a committee of the American Psychological Association and the National Research Council, and are applicable to men in the mass, say up to 500 at one time. The results are valuable for determining a man's probable limitations in various occupations, and for determining average intelligence standards for different kinds of work. In all the tests engineers stood at the head of the list. These tests have relation to intelligence only, and do not refer to temperament, moral qualities or effect of special training. So far as the Army was concerned, the tests showed that intelligence was the most important single factor in military success; and it is believed that good results can be obtained by their application in industry.

Fine Crushing in Ball-Mills was presented at some length and in mathematical form by MR. E. W. DAVIS. The author conducted his tests with Mesabi magnetite, sp.gr. 3.4 and hardness 7. The following deductions are drawn from more than 150 operating tests:

1. In every case an increase in the tonnage fed to the mill resulted in an increase in the efficiency.
2. In every test the limiting factor of the test was not the ball-mill, but some auxiliary apparatus, usually the classifier.
3. All tests point to the fact that the ball-mill is a machine of very large capacity, especially if it is provided with proper auxiliary apparatus.
4. Classifying and pulp-handling machines that will handle a circulating load of at least 500 per cent of the original feed should be provided.
5. Closed-circuit crushing is more desirable than open-circuit.
6. The real advantage in closed-circuit crushing lies in the fact that the maximum size of particle is nearer the average size of particle discharged from the circuit.
7. Two-stage crushing is more efficient than single-stage.
8. The real advantage in two-stage crushing lies in the fact that the ball charges can be adjusted more nearly to the required conditions.
9. Two-stage open-circuit crushing does not present this advantage, as the maximum-sized particle in both stages is more nearly the same.
10. The proper adjustment between size of balls and speed of mill can be secured by an examination of the classifier sands.
11. If the balls are large or the speed is high, the screen analysis of the classifier sands will be crowded at the finer sizes.
12. If the balls are small or the speed is low, the screen analysis of the classifier sands will be crowded at the coarser sizes.
13. From the data at hand, the indications are that the best efficiency is obtained when the screen analysis of the classifier sands shows a minimum of crowding at any size.
14. Balls no larger than necessary should be used, as this makes it possible to charge the mill with the greatest number of balls.
15. Balls smaller than can crush the larger particles of ore should not be kept in the mills, as they take up space, absorb power and do inefficient crushing.

Following are some of the conclusions as to operation of ball-mills:

1. By use of formulas the proper theoretical speed for the operation of the mill may be computed.
2. This speed is correct only when there is no slipping between the charge and the lining of the mill, and when the pulp is not so thick as to produce strong adhesion between the particles.
3. In actual practice it may be found that more effective crushing can be done at some other speed, but it would appear that the variations above or below this theoretical speed should be small.
7. The amount of crushing done depends upon the number of blows struck and the work done at each blow.
8. The number of blows struck can be increased by increasing the number and decreasing size of balls.
9. The work done at each blow can be increased by increasing the weight of the ball and by increasing the diameter of the mill.
10. From this it follows that mills of larger diameter should be charged with smaller balls and mills of smaller diameter with larger balls, when working on the same feed.
11. The proper operating speed of a ball-mill varies inversely as the square root of the diameter.
12. The proper operating speed of a ball-mill increases as the size of the ball load increases.
13. Due to interference between the balls, the volume of the charge should not be over 60 per cent of the volume of the mill.
14. Unless great care is exercised to prevent slippage, the volume of the ball charge should not be less than 20 per cent of the volume of the mill.
15. It would then seem that a ball charge that occupies between 30 and 50 per cent of the volume of the mill will give the most satisfactory results.
16. In an 8-ft. (2.4-m.) mill running at 22 r.p.m., with a 28,000-lb. (12,700-kg.) charge of 2-in. (50.8-mm.) balls, there will be an average of about 1,000,000 blows per minute; each of these blows will be equivalent to dropping a 2-in. ball 5 ft. (1.5-m.).

Conclusions on ball wear are summarized as follows:

1. In any mill, the rate at which the weight of any ball decreases is directly proportional to its weight.
2. In any mill, the rate at which the diameter of a ball decreases is directly proportional to its diameter.
3. In any mill, the rate at which the surface of any ball decreases is proportional to its surface.
4. Since the rate at which a ball loses weight varies as the work done upon it in the mill, it follows that the work done in wearing (or crushing) the ball varies as the weight of the ball. This is seen to be Kick's law.
5. It then appears that Kick's law holds true for the ball wear in a rotating mill.
6. The natural tendency is for the small balls to accumulate in the mill charge.
7. Since these small balls do very little crushing, and exclude ore and larger balls from the mill, if allowed to accumulate too long, a marked decrease in crushing efficiency will result.
8. Since the large ball is just as likely to strike the small pieces of ore and the small ball is just as likely to strike the large pieces of ore as the reverse, it would seem that all of the balls should be of a size to crush any of the particles of ore.
9. This means that the balls should be as nearly as possible of a uniform size.
10. Since spheres of uniform size provide the greatest amount of interstitial space, a mill charge composed of balls of uniform size will allow freer migration of the ore particles than a charge containing balls of different sizes.

Methods of Concentrating Manganese Ore were considered very broadly in a paper by MR. EDMUND NEWTON. The author gave no specific examples of concentration, but offered the following outline of methods that might be used, with due regard to the nature of the ore, size of deposit, location and other economic factors:

Simple Methods of Concentration:
- (*a*) Selective mining.
- (*b*) Hand picking.
- (*c*) Jigging.
- (*d*) Screening.
- (*e*) Log washing.
- (*f*) Water classification.
- (*g*) Roughing table treatment.
- (*h*) Slime table or vanner treatment.
- (*i*) Pneumatic separation.
- (*j*) Combination of two or more of the above.

Complex Methods:
- (*a*) Magnetic separation:
  1. Without preliminary thermal treatment.
  2. With preliminary thermal treatment.
- (*b*) Electrostatic separation.
- (*c*) Hydrometallurgical processes:
  1. Leaching with various acids. Precipitation by chemical substances.
  2. Leaching with various acids. Precipitation by electrolysis.
  3. Leaching with various acids. Evaporation of solution and heat treatment in rotary kiln.
- (*d*) Preliminary thermal processes:
  1. Drying, to remove hygroscopic moisture.
  2. Calcining, to remove carbon dioxide or combined water.
  3. Agglomerating fine concentrates to make them desirable for blast-furnace use.
  4. Volatilizing manganese at high temperatures in the presence of certain constituents which form readily volatile compounds.
  5. Direct reduction of oxides by carbon, under temperature control.
- (*e*) Miscellaneous processes:
  1. Flotation.
  2. Use of heavy solutions.

MORNING SESSION OF INSTITUTE OF METALS

Two sessions of the Institute of Metals Division occurred on the first day, largely attended by an enthusiastic group. Illustrating the wide range of interest, the feature of the morning was a discussion of the amorphous theory, and of the afternoon an appreciation of new methods in casting and melting manganese bronze. DR. ZAY JEFFRIES' paper entitled "Effect of Temperature, Deformation and Grain Size on the Mechanical Properties of Metals" is but one of a series of recent and important contributions to the knowledge of crystalline and amorphous phases of metal, and the mechanism of failure. The author cites experiments performed by himself and others showing diverse relations between strength, elongation and hardness as influenced by the rate of loading, temperature and past history, and then endeavors to explain many puzzling anomalies by a simple relation between cohesion and temperature of the metallic constituents. The subject is far too intricate for a short abstract, and is reserved for a later presentation at some length, especially since the amorphous theory as expounded by Jeffries is not universally accepted—as eminent an authority as Prof. Mathewson of Yale expressing his vigorous dissent from the idea of a truly amorphous phase, leaning rather toward a conception that a sub-crystalline superamorphous layer somewhat continuous with its surrounding metal is the cement which holds the crystalline aggregate together. Of interest to iron and steel metallurgists is the evidence drawn from Jeffries' curves between respectively, tensile strength, elongation or ductility and temperature. These show discontinuities at ranges between 30 and 300 deg. C., not entirely concordant, it is true, yet they present peculiarities easily explainable by the assumption of a low-temperature allotrope. This evidence may be sufficient to convince many metallographists who would like to postulate this phase.

VOLATILIZATION OF CUPROUS CHLORIDE ON MELTING COPPER CONTAINING CHLORINE

MESSRS. S. SKOWRONSKI and K. W. MCCOMAS, of the Raritan Copper Works, presented their results on the "Volatilization of Cuprous Chloride on Melting Copper Containing Chlorine." This is of much present importance, since any copper-leaching process giving chlorides either from the ore or solvent will electrolytically deposit cuprous chloride on the cathodes, which, if readily volatile, would represent large metal losses. It has long been known that in melting copper known to contain chlorine, the fumes evolved have been sufficient to interfere with the charging or to drive the workmen from the building, and that flue dust from furnaces melting copper with but traces of chlorine will analyze up to 15 per cent cuprous chloride. Experimentally, a small amount of copper containing various percentages of chlorides was melted and the volatilized copper chloride determined. The results, figured to a ratio of volatile copper to volatile chlorine, varied from 1.66 to 1.76 when melting under carbon dioxide, air, or furnace gases, as compared to a theoretical figure of 1.79 for total volatilization, and therefore it is considered that under present refinery practice all cuprous chloride in cathodes will be volatilized and lost to the bath.

A short paper on "Automatic Copper Plating" by MR. J. W. RICHARDS called for some comment. Especially MR. A. SILVERMAN reviewed the method of copper-coating steel by casting copper, brass or cupro-nickel around a red hot steel core, then rolling or drawing the composite bar. He exhibited samples of the finished

material, which has been adapted to a wide variety of uses.

Other contributions which were read by title were an important description of the results obtained in the "First Year of Leaching by the New Cornelia Copper Co.," by MESSRS. H. A. TOBELMANN and J. A. POTTER; "Die Castings and Their Application to the War Program," by MR. CHARLES PACK; "Two Instances of Mobility of Gold in Solid State," by MR. EDWARD KELLER; and "Notes on Electric-Furnace Problems," by MR. J. L. MCK. YARDLEY.

AFTERNOON SESSION OF INSTITUTE OF METALS

The feature paper of the Institute of Metals Division's afternoon program was MR. P. E. MCKINNEY'S paper on "Manganese Bronze." Mr. McKinney is metallurgist at the naval gun factory in Washington, and describes the methods he has used for over three years in the manufacture of highest grade manganese bronze castings by melting scrap materials in an open-hearth furnace. For instance, 250 lb. of a manganese hardener (scrap copper alloyed with ferromanganese) is placed in the bottom of the furnace; next is a ton of dross and skimmings from the cartridge-case plant and 400 lb. of zinc dross from the galvanizing plant. Seventy-five pounds of charcoal for reducing agent is next spread over the charge, and the balance of the heat added—principally yellow-brass turnings, zinc scrap, foundry scrap and skimmings. Common salt (80 lb.) is used to flux the dirt and collect oxides of iron and manganese. The reactions which form a bath of quiet metal from this mixture are similar to those in old-fashioned calamine-brass manufacture, while the small amounts of iron, tin and lead ordinarily added to virgin metal already exist in the waste materials used. Over a million pounds of castings per year have been made in this manner, ranging from small work to pieces of nearly ten tons, and while the lead content ordinarily is much above naval specifications, test bar results have been quite high, and the finished castings have withstood severe war service—which, doubtless, is the end and aim of a specification.

MR. J. L. JONES emphasized that the method could hardly be used with success in any but a large foundry, which has available a large supply of scrap of known origin and uniform analysis. Close chemical control is necessary, of course, and the speaker emphasized particularly the necessity of Mr. McKinney's practice of deoxidizing with aluminium and casting the original melt (figured to make a correct alloy) into ingots, which could then be analyzed and remelted with necessary corrective additions.

MANGANESE BRONZE MANUFACTURE

MR. G. H. CLAMER outlined interestingly the history of manganese bronze manufacture since "Parson's metal" was first made by the Cramps some twenty-five years ago. In particular he pointed out that this paper controverted the idea that a reverberatory is a bad place to make brasses, on the basis that it was hard to regulate the atmosphere and large oxidation losses in zinc and aluminium would therefore result. Especially the latter produces an infusible oxide which is hard to flux and is liable to segregate in the casting. The analyses quoted showed much higher lead than would be accepted from private manufacturers, and if the Government specification would be changed to correspond with the demonstrated facts, much waste and second grade metal could be utilized by all bronze-makers.

Many speakers contributed bits from their experiences. Especially was it emphasized that the results from test bars, whether cut from coupons, sink-heads, or hollow-milled from the body of the piece, depended to a preponderating extent upon molding practice; that is, of two of the same patttern, cast from the same heat at the same temperature, one, if properly gated and with correct risers and heads, would test perfectly, while the other, badly gated and with inadequate allowance for shrinkage, would test very low.

MESSRS. W. H. BASSETT and C. H. DAVIS, recognizing the impossibility of testing thin sheets in a Brinell machine, have worked out "A Comparison of Grain-size Measurements and Brinell Hardness of Cartridge Brass." Fig. 1 gives their results. At low annealing temperatures the grain size is influenced by the grain size of the previous anneal; but from 0.060 mm. upward the relation is unaffected by the history of the

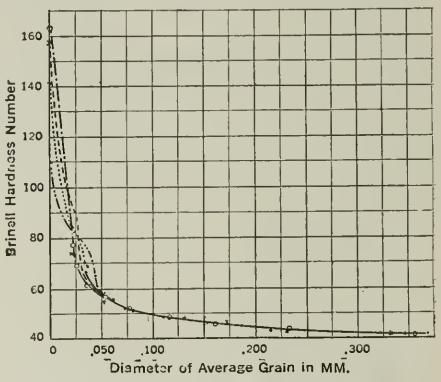

FIG. 1. BRINELL HARDNESS INDICATES GRAIN SIZE FOR ANY GIVEN BRASS IN THE ALPHA PHASE

piece. The grain size and the Brinell hardness change progressively with the percentage of copper in brasses, but their relation is a constant for each brass mixture in the alpha phase. Major White in commenting upon the fact that grain size measurements, as specified for sheets less than 0.1 in. thick, are slow and subject to the operator's personal equation, said the Bureau of Mines had worked up a "Baby Brinell" which was capable of testing thin sheets satisfactorily, and would prove valuable to quick, easy and adequate inspection of thin brasses.

Many of the metallurgists present had heard of colloids, and some had a dim conception of what the term was designed to express, but few had ever considered that such matters had definite application to their science until it was pointed out in a brief but very suggestive paper by MR. JEROME ALEXANDER on "Metals and Alloys From a Colloid-chemical Viewpoint." Particularly he urged thought toward development of methods to make sufficiently thin sections to be used under the ultramicroscope, with a view of attacking moot problems in the constitution of certain metallic phases.

Unusual occurrences abounded at this New York meeting. Not the least was the appearance of a feminine author, MISS LILIAN ERSKINE, of the New Jersey Labor Bureau, with a paper on "Standards for Brass and Bronze Foundries and Metal-finishing Processes." The paper dealt largely with the adequate provision of light, heat and air for the workers' health and efficient production in such plants—conditions not altogether easy to maintain at all times and seasons and therefore almost universally neglected. An appreciation of the money value of such comforts is spreading, however, and those who rebuild old or construct new foundries would do well to examine Miss Erskine's paper, or better, study the exhaustive material available at the New Jersey Bureau.

MORNING AND AFTERNOON IRON AND STEEL SESSIONS

Perhaps the most interest of the second day's sessions on metallurgical subjects was exhibited over the question of "Flakes," a defect in high grade steels which has recently caused much trouble. This subject is treated at length elsewhere in this issue and therefore it will not be repeated here.

MR. H. E. DOERR presented a short paper entitled "Does Forging Increase Specific Density of Steel?" describing experiments on several sound steel ingots in forged and unforged condition. Forging is shown to increase the density but very slightly, and thus controverts the popular conception, which would be true only for very spongy steel. MR. J. S. UNGER presented work indicating the opposite state of affairs to be true. As DR. H. M. HOWE pointed out, however, the specific gravity of steel is the result of various factors. As the carbon content and its heat treatment vary, the specific gravity changes owing to the different heaviness of cementite and the allotropes of iron. Gas cavities existing in cast metals may be closed in forging, increasing its weight, but on the other hand, forging has an almost irresistible tendency to open up a central pipe.

STATIC, DYNAMIC AND NOTCH TOUGHNESS

In "Static, Dynamic and Notch Toughness," the author, PROF. S. L. HOYT, called attention to the oftendisregarded fact that toughness is not synonymous with ductility, and that in general ordinary physical tests do not give an indication of the shock-resistant qualities of a piece of metal, especially if it is key-seated or used in the "notched" condition found at many places in modern machines. He therefore pleads for the adoption of a notched-bar impact test to determine a real factor of fitness for materials to be used in such ways. Various members contributed to the discussion, drawing attention to the extreme care to be exercised in order to get concordant results from shock tests, and to the need of an investigation to establish relationships between shock and fatigue tests. DR. MATHEWS emphasized particularly that internal notches, such as non-metallic inclusions, flakes or blowholes, are really more important in their effect on shock testing and actual service than are the external notches appearing by design.

MR. R. S. ARCHER gave the results of his work on the "Development of Grain Boundaries in Heat-treated Alloy Steels." It was found impossible to develop grain size in heat-treated chrome-nickel steels by ordinary etching agents. If, however, the steel be etched about ten minutes in a fresh solution of picric acid in ethyl alcohol, and the carbonaceous smudge polished off on moist broadcloth, the internal structure and any defects present were developed quite well, together with boundary "ghosts" of former crystals broken up into the extraordinarily fine crystals of hardened metal.

WATER-COOLED EQUIPMENT FOR OPEN-HEARTH STEEL FURNACES

Details of doors, frames, buckstays, port- and wall-coolers, valves and dampers were presented by MR. WILLIAM C. COFFIN, in "Water-cooled Equipment for Open-hearth Steel Furnaces." The author pointed out that the use of water-cooled equipment was, first, to hold the furnace to its lines, either in order to smelt correctly, or to relieve the brickwork from undue strains; second, to maintain the metal parts in question, and third, to increase the operators' comfort. On the other hand, the practice should not be elaborated to the point where the furnace would be cooled—in other words, the fuel burned in the furnace should refine metal and not melt refractories or heat cooling water. Practically, the desired result would be had in doors, for instance, by a one-course lining which fuses on its inner surface and burns back to a certain point where the heat radiating slowly outward is just sufficient to keep the hot portion solid. Ports are more difficult to protect since splashes of oxide flux the silica brick at temperatures as low as 1200 deg. C. At any rate, as pointed out by MR. UNGER, water cooling may be pushed to an extreme where the cost of fuel, maintenance, cooling water and the circulation of same is more than the savings in refractories, delays and metallurgical performance. As to materials of construction, welded steel plates are almost ideal, being uniform, thin and therefore conductive, strong and permanent. Cast iron, on the other hand, must be made with thick walls which are less conductive, therefore they warp out of shape and crack. Copper is somewhat more satisfactory, but it is expensive and difficult to cast in large masses.

MESSRS. J. S. MCDOWELL and R. M. HOWE presented a paper on "Basic Refractories for the Open Hearth," in which they gave results of laboratory tests on materials prepared from American dolomites and magnesites, largely used, as is well known, as substitutes for the imported material. While small-scale testing can never duplicate furnace conditions, the authors' work indicates that most satisfactory refractories may be made from Western magnesites low in lime, while non-slaking fettling may be made by coating granules of impure dolomite with basic open-hearth slag at high temperatures.

TWO NOVEL PROCESSES DESCRIBED

Two novel processes of manufacture were described by MR. J. E. JOHNSON, JR., and DR. J. W. RICHARDS, in their respective papers on "Davidson Process of Casting Formed Tools," and "Shimer Case-hardening Process." The first recorded the successful attempt to cast sound tools of alloy steels practically to shape which can be annealed, finished by light machine cuts, hardened and ground. Samples of intricate tools made by this cheap method were exhibited which comparative tests show to be equal to tools cut from rolled bars after

the usual method. Evidently successful tool-making by casting requires a thoroughly well-killed melt (effected by the use of a secret composition), producing no blow holes from dissolved gases or from green molds, fluid metal for making sharp castings, and a final metal satisfactory in physical properties. DR. RICHARDS' paper noted a successful war-time substitute which equals the case-carburizing action of the usual fused cyanide bath. MR. SHIMER found that a melt of easily fusible salts of commercial purity such as sodium, calcium and barium chloride will absorb calcined lump calcium cyanamide, with a lively evolution of gas, which effervescence continues as long as the bath has carburizing qualities. The rationale of the operation is as yet unknown.

A Metallographic Investigation of Transverse-Fissure Rails

MR. G. F. COMSTOCK in "A Metallographic Investigation of Transverse-fissure Rails, With Special Reference to High-phosphorus Streaks," attempted to harmonize somewhat the views of various rail-failure disputants, one group holding transverse fissures to be from fatigue, others insisting them to be from poor quality. The author carefully examined 24 fissured and 12 sound rails of known history, examining and classifying their sulphur prints, inclusions of alumina and of slag, and the amount of free cementite and ferrite exhibited, without finding any general relationship between such defects and the location or presence of transverse fissures. When etching polished steel sections taken normal to the fissure with Stead's cupric chloride reagent, the thin film of copper ordinarily deposited on normal metal was absent on segregated phosphorus streaks, in many cases the most pronounced of which passed through the fissure's nucleus, and fissured rails were pronouncedly more streaked than sound ones. DR. P. H. DUDLEY vigorously contended that transverse fissures were not fatigue failures, since normal wheel loads and track construction induce stresses far below the elastic limit, and result from abnormal metal only. Since but one break in 1585 is due to this cause, it is practically impossible to investigate the phenomenon in any way but by tracing the rail back to the mill. This done, it seems that 90 per cent are from direct-rolled rails. Reheating the blooms results in better rails either through allowing more time for the slow diffusion of phosphorus, as suggested by Comstock, or more probably by healing the fractured structure caused by the blooming mill, or by producing more uniform hot bed annealing and making necessary less gagging in the finishing department. As MR. G. M. DAVISON pointed out, a method should be devised to detect internal faults after the rail was in the track and before it caused a wreck. Electrical and magnetic tests had apparently not proved as satisfactory as anticipated. In any case, metallographists would have to demonstrate the undoubted existence of phosphorus in the streaks and to determine its rate of migration at reheating temperature before Mr. Comstock's proposal could be accepted, in view of the fact that phosphorus in modern open-hearth rails is but 0.03 per cent, while older bessemer rails, with four times as much, are practically free from transverse fissures.

The most notable feature of the session of the National Research Council was a clear analysis of the metallurgical practice necessary to produce sound, high grade alloy steels for munition purposes presented by DR. H. M. HOWE as an abstract of the unpublished "Report of Steel Ingot Committee."

His discussion applied only to the production of highest grades of steel containing perhaps 3.5 per cent of nickel, with or without chromium, from pure materials, and may be summarized by the phrase "refine hot and pour cool." The cold charge melts at a temperature of about 1440 deg. C. in approximately 6 hours after charging, whereafter the temperature is run up rapidly to the maximum which the furnace will stand—in the neighborhood of 1670 deg. C. This is to deoxidize the bath largely by its contained carbon, so that the products may escape from the melt and furnace as a gas. When the refining is completed the temperature is dropped very rapidly to stop the further oxidation of the carbon, so that the analyses returned to the furnaces some half-hour later may have some meaning. If these agree with the specification, ferromanganese is added to the bath essentially to add manganese to the steel—no more than 10 or 15 per cent of it should be oxidized at this stage, since the resulting slags are not entirely eliminated from the steel, causing inclusions and ghosts. About ten minutes afterward, when the temperature of the bath has dropped to the required point, the heat is tapped, cooling materially in the ladle, where it is held perhaps 20 minutes for it to reach its correct pouring temperature, which latter is of the greatest importance. Slow pouring is also essential: A rapid pour chills a solid skin of metal next the mold, the mold is later heated considerably by the interior hot metal, it expands, leaving the thin skin unsupported. This cracks from hydrostatic pressure and liquid iron flows from the inside. Slow pouring gives thicker walls at the bottom, capable of withstanding the interior pressure; it also reduces piping by supplying the pipe, growing from the bottom upward, with fresh metal. Pouring at too low a temperature must be avoided as well—a point somewhat below the liquidus is best where the metal is in the form of a thin emulsion, thin enough to form smooth and strong, thick walls against the mold but not mushy enough so that inclusions cannot be slagged off.

Distinction Made Between "Ladle Steel" and "Furnace Steel"

In the discussion of this and the two following papers a sharp distinction was made between "ladle steel" and "furnace steel"; one made with additions to open-hearth metal during tapping, while the latter denoted that all deoxidizers were charged in the furnace. DR. HOWE recognized the fact that tank-steel may readily be made economically by ladle addition, whereas cannon-steel certainly could not. Since metal is tapped below the liquidus, any solid ladle addition first chills a thick shell of solid steel about it, which later must be melted before diffusion can begin. MR. H. D. HIBBARD thought that for safety steel makers should adopt the rule to make only the best steel, but MR. F. N. SPELLER pointed out that this would hardly hold in all cases, since, for instance, certain welding steels cannot be produced by electric-furnace methods. In other words, impurities may at times be of value, and at other times

be of no harm—sash weights of melted tin cans are thoroughly good.

Two papers on manganese were read which would have been eagerly devoured six months ago, but to-day appear to be largely of historical interest. MR. P. H. ROYSTER'S study of the "Production of Ferromanganese in the Blast Furnace" presented a table of operating quantities gathered from eleven furnaces, wherefrom he draws information as to approved practice. Contrary to expectation, a high blast temperature does not appear to be as important as a basic slag in influencing the amount of manganese lost at the cinder notch. Leaving the alumina out of consideration, the author finds the ratio of bases to silica for good slags is usually 1.5, although it may reach the figure 2. Experience also bears out the common impression that it is easier to reduce losses by reducing the slag volume rather than the percentage of manganese in the slag—in other words, use only the purest ore, stone and coke obtainable. "Use of Manganese Alloys in Open-hearth Practice" was studied by MR. S. L. HOYT, in which he described substitutes for 80 per cent ferro. First, recarbonization and deoxidation have been effected simultaneously by use of a cupola-melted mixture of spiegel and pig, analyzing perhaps 6 per cent Mn and 4 per cent C. Second, use a high-manganese charge (scrap, ore and pig iron) and run the furnace with an 80 per cent manganese slag so that at the end the metal retains 0.30 per cent Mn. In such practice the phosphorus is early removed and slagged as calcium phosphate, and the heat finished at a high temperature. Third, silicospiegel can be easily made in the electric furnace from siliceous ores. Low-iron ores are available in the Rocky Mountains, but the high-iron ores so abundant in the Cayuna range are not so desirable, since a much greater quantity of the resulting spiegel is required to do the work. Information as to the use of this alloy is meager, although it is unquestionably suitable for acid casting practice. Three years' experience at one steel plant alternating silicomanganese with ferromanganese plus ferrosilicon shows the former to be somewhat more economical in alloy consumption, and to make for more uniform practice. It is doubtful, however, whether it could safely be used as a furnace addition in basic open-hearth.

EFFECT OF COLD-WORKING AND REST ON RESISTANCE OF STEEL TO FATIGUE UNDER REVERSED STRESS

MESSRS. H. F. MOORE and W. J. PUTNAM submitted a paper on "Effect of Cold-working and Rest on Resistance of Steel to Fatigue Under Reversed Stress." Their results show no marked benefit of a short period of rest on the fatigue strength of steel. Tests also indicate that an increase in strength of medium steel due to cold-working does not necessarily indicate increased resistance to fatigue, while the fatigue-strengths of cold-rolled and annealed steels apparently converge as lower stresses are used, even though the annealing temperature is of large importance. Most excellent moving microphotographs were exhibited, showing the development of slip bands under heavy alternating stresses, together with the progressive extension of incipient cracks. The methods and lenses for making these remarkable pictures were developed by Prof. A. G. ELDRIDGE of the University of Illinois.

Government's Policy in Sale of Surplus Supplies

REPRESENTATIVES of the War Department, the Navy Department and the Geological Survey have had a conference concerning the policies which they should follow. After this conference the Director of Sales, War Department, made the following statement:

1. The fundamental purpose of the conference was to determine, first, what each department of the Government had to sell.
   (a) Any department of the Government desiring material that any other department of the Government may have to dispose of should have an opportunity of obtaining it.
   (b) We should control our methods of selling in such a way as not to permit different departments of the Government to compete one against the other.
   (c) We must dispose of all surplus so as to disturb industrial conditions to the least possible degree.
2. It will first be necessary to give each bureau a record or statement of the surplus on hand.
   (a) We hope to have a more or less complete inventory by Feb. 15.
3. The War Department policy is:
   (a) To dispose of surplus materials to other bureaus of the War Department and other departments of the Government.
   (b) To sell to the contractor in whose possession the material is at a fair price.
   (c) To approach the producers or consumers of a particular material with the idea that they take it over at a fair price and dispose of it at a fair price.
   (d) To dispose of it through ordinary trade channels.
   (e) To put it on the open market.
4. Our general policy is to release small quantities in those instances where it is to the War Department's advantage to release to avoid the payment of storage charges or demurrage, and to accommodate those who desire to buy. In other words, our policy is one of slowly selling our commodities to disturb general market conditions as little as possible. We are not actuated by any desire to dump our surplus on the market without regard to the industry interested. Our general policy is to obtain as much from the sale of this surplus as we can. The trade should distinctly understand that it is not the policy of the Sales Department to sell property to any one for speculative purposes.

Conferences have been held relative to the disposition of surplus brass, copper and lead now on hand in the various bureaus of the War Department. It is expected that an agreement will be made with copper producers that will permit the Government to feed into the market its surplus of copper and brass in such a manner as to obtain fair prices for the Government without upsetting the market.

The situation with regard to lead is even more favorable, as the surplus amounts to only a few thousand tons, which is but a small proportion of a year's output. The same agreement will be made, however, and every precaution will be taken not to disturb the equilibrium of the market and at the same time to obtain the highest prices possible.

War Took All Candidates for Degree

There will be no candidates for the degree of Ph. D. in chemistry at Johns Hopkins University in June on account of the interruption in the work due to the war. However, a number will come up Feb. 22, 1920. The chemistry department of the university is rapidly recovering from the effects of the war and already twenty-one graduate students are devoting full time to chemistry.

Flakes in Alloy Steel

An Outline of Papers and Discussion of This Important Defect Presented at the New York Meeting of the American Institute of Mining Engineers—Divergent Views of Howe, Clayton, Rawdon, Foley and Laney

CONVINCING evidence of the commercial importance of metallographic science was exhibited at sessions of the American Institute of Mining Engineers, where veteran steel makers listened most carefully to technical papers on the origin and control of a relatively new defect known as "flakes." This subject is of much importance on account of the extremely large number of rejections in shops manufacturing nickel and nickel-chromium ordnance material. The control of the defects is most difficult and the conflicting evidence leads to the belief that in some instances at least their appearance in test bars was due to the method of testing and to the personal equation of the inspector. Two important papers on this subject, therefore, attracted much attention. First, C. Y. Clayton, F. B. Foley and F. B. Laney co-operated in presenting a contribution on "Flaky and Woody Fractures in Nickel-Steel Gun Forgings," and H. S. Rawdon presented somewhat conflicting views in his paper entitled "Microstructural Features of Flaky Steel." The whole matter was admirably summarized by Dr. H. M. Howe in his oral presentation of a report by the Steel Ingot Committee, National Research Council. In addition to these gentlemen, Messrs. Unger, Mathews, Stevenson, Speller and others participated in the general discussion.

Flakes are variously known as "flakes," "snow-flakes," "scabs," "lemon spots," "goose eggs," "silver streaks," and are often associated with a fibrous or woody structure in the fracture. Of course, the terminology is not yet precise. For instance, Mr. Rawdon illustrates silver streaks as shown in Fig. 1, and notes that each has in its center a tiny bit of greenish slag. Silver streaks are familiar to many as crystalline fractures due to presence of slags. The other defects are often associated with slag and some men view slag as their controlling cause. But flakes and fibrous structure have been found many times in the cleanest steel. Flakes are most common in chromium and nickel-chromium steels, which are notoriously quite tender under treatment, and in practice have been controlled and eliminated to an extent by well-regulated heating practice. They are supposed to be cracks within the steel itself, and as such would not be found in forged easily welded carbon steels, while a small percentage of nickel in the analysis reduces the weldability markedly. Evidence was cited that their presence is not controlled by the shape of the ingot, casting practice, size of ingot, reheating practice or per cent of reduction. Sometimes a plant would not be troubled with rejections on acount of flaky steel for some time after starting munition manufacture and then flakes would suddenly appear. For instance, Mr. Stevenson cited his own experience that no trouble was encountered during their early operations when they made steel from low-phosphorus scrap. Later as the croppings accumulated the charge was modified to consist of nickel steel scrap and low-phosphorus pig, whereupon flaking became very severe.

FIG. 1. CHROME-NICKEL STEEL WITH SILVER STREAKS IN FRACTURE —ACTUAL SIZE

Macroscopy and Microscopy

Flakes appear in a fracture as bright, silvery spots or areas surrounded by a normal granular field (Fig. 2). Especially is this the case when breaking a specimen which has a refined or hardened grain. It is apparently a spot of more massive or coarsely granular material than its surroundings, but under low-powered magnification there are no sparkling cleavage planes, but the corners and edges are rounded and smooth, suggesting surfaces of squeezed crystals. Clayton believes that the flake passes through the ferrite existing between the sorbitic grains, and partly through the grains themselves—following here the plates of ferrite, producing the Widmanstättian structure commonly observed, and very evident in Fig. 3. Rawdon, on the other hand, thinks that they are remains of the original crystalline faces formed on solidification, which have failed to unite, even during the kneading action of subsequent working.

Presence of the discontinuity known as a flake can be demonstrated after macroscopic etching. Thus, Fig. 4 gives their appearance in a polished transverse surface. Ordinary etching solutions attack the metal near the flake more quickly than elsewhere and leave tiny open cracks. Copper bearing solutions develop them—in fact such media always bring out non-homogeneity such as dendritic crystals or streaks. In a fracture the flakes oxidize less rapidly than the surrounding metal.

Finally, radiographs exhibit white lines which, on breaking the specimen, prove to mark the location of flakes; evidently the metal is more transparent to rays along these planes.

Microphotographs of defective steel always indicate a lack of grain refinement; sometimes this is very striking. Streaks or areas showing variations in grain size may be noted in less infected specimens. Clayton feels that the presence of flakes in exceptionally clean steel is evidence that they are not due to inclusions, while Rawdon apparently leans toward the idea that slag is materially responsible. He finds the filiform ends of coarse flakes to consist of extremely fine films of slag. This point is rather hard to determine, since, if flakes are intercrystalline defects, here, of course, would also be found any slag inclusions or segrega-

tions—an association which might indicate nothing as to the origin of the flakes. If the plane of flake intersects the polishing plane, it appears under high magnification as a black streak around the grain boundaries, thus following any ferrite mesh which exists. Microchemical work at the Bureau of Mines also indicates that the flake areas are higher in phosphorus and carbon than normal metal—differential action by copper-bearing etching reagents always exists along the borders of a flake, as already noted. Rawdon, while admitting the fact that the defect follows grain

FIG. 2. FINE GRANULAR FRACTURE SHOWING 59 PER CENT COARSE FLAKE × 3.5

boundaries, gives photographs such as Fig. 5, which show that a flake has no depth. Clayton and his associates lay much stress on the fact that they always find much evidence of overheating in defective material, such as Widmanstättian structure and spiny ferrite, drawing from this fact a basis of their theory as to their nature and proper control.

Physical Tests

The bulk of the work reported was performed on gun forgings containing 0.38 per cent carbon and 2.9 per cent nickel, with or without a small amount of chromium. When loading a defective test bar of this composition in tension, small cracks develop on the surface normal to the pull. This has led to the widespread idea that flakes are incipient cracks, a conclusion which is hard to reconcile to the unchanged elastic limit shown in the attached table.

TABLE I—PHYSICAL PROPERTIES OF GUN FORGING

	Minimum Specifications	Good Bars	Average of 182 Flaky Bars
Tensile strength	95,000	101,580	97,282
Elastic Limit	65,000	68,260	68,120
Elongation	18%	19.4%	11.6%
Reduction in area	30%	37.5%	20.5%

NOTE—The elongation and reduction in area of the flaky bars are extremely variable, depending upon extent of the defects at the breaking point.

Dr. Howe suggests that the constant elastic limit may be explained thus: Suppose a flake to be an internal area of small strength normal to the pull. The absolute value of the elastic limit would then be reduced according to the area of this reduced section. But as the flake has no depth, the elongation caused when this weak section passes its proportional limit is but a fraction of a thousandth of an inch. No contraction in area is possible in metal strongly supported on all sides, and therefore the extra stretch is not detectable to the extensometer, which naturally is not affected until the specimen gives over a considerable length.

Woody structure appearing in fractures is thought by Messrs. Clayton, Foley and Laney to be much different from flakes, and to emanate from the original dendrites in the ingot. Forging or rolling will elongate these crystals into parallel longitudinal lines giving very low transverse ductility. Such laminated structure is very persistent, annealing for days being required for its elimination. If this be a true explanation of woody structure it may evidently be cured by variable rotation of the ingot, which has been proved to reduce columnar solidification.

Are Flakes Formed During Reheating?

Clayton then proceeds to discuss the possible causes of flakes. First, they may be due to foreign inclusions (which possibility was disposed of above). Second, gas inclusions and cavities may be responsible—an attractive hypothesis which warrants much further investigation. Third, their association with ferrite may indicate them to be due to a local decarbonization resulting from churning in of oxide films formed on pouring. However, extremely few oxide inclusions were found. Fourth, the local segregation of non-ferrous elements to be expected at crystalline boundaries may be responsible for flakes. This is a contributing cause of low-melting areas, postulated by Clayton's hypothetical explanation. Fifth, the shape of the ingot and

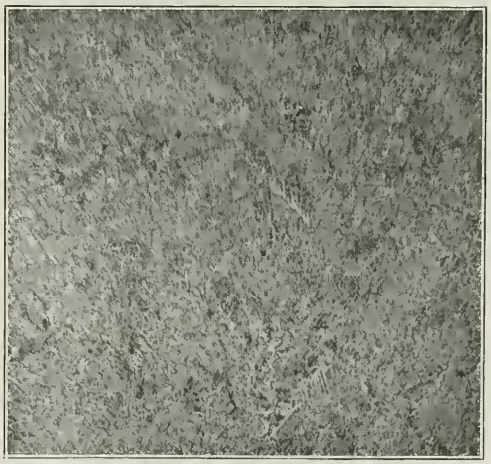

FIG. 3. MICROSTRUCTURE OF FIG. 2. FERRITE ROUGHLY OUTLINING PREVIOUSLY EXISTING COARSE NETWORK. × 260

the forging dies does not seem to have much influence. Sixth, flakes may be ruptures in the ingot caused by the differential coefficient of expansion in heretogeneous metal. This is approximately Rawdon's idea, he being ably seconded by Dr. Howe. Lastly, the theory which appeals most to Clayton and his associates is that flakes are due to overheating and non-uniform heat preparatory to forging.

Their experience with shop conditions leads them to believe that forging these special steels is ordinarily done at too high a temperature. For instance one

poorly designed heating furnace was run at 1370 deg. C. at the hot end, producing 70 per cent rejections in steel forged from this temperature, but much better results from the cooler portions of the hearth. If the billet starts too hot, it will be finished at too high a heat, giving a typically coarse grain always accompanied by Widmanstättian structure (Fig. 6). On the other hand with a light reduction under the hammer the temperature can be kept as low as 1040 deg. C., with a resulting structure shown in Fig. 7, and a total absence of Widmanstättian lines or other evidences of burning even under high magnification.

From this basis Clayton ascribes flakes to be ultimately due to slow diffusion of ferrite. In heating coarse-grained hypo-eutectoid steel the first transformation occurs at Ac_1 where pearlite areas revert to austenite of eutectoid composition. Alpha iron envelopes are absorbed at Ac_{y_2} but owing to slow diffusion the resulting austenite is heterogeneous even upon superheating, retaining a high-carbon core where previously was the center of the larger pearlite grains. Here is where fusion starts, and in forging these plastic spots are flattened out, persisting as films and boundaries to which excess ferrite is precipitated. Sorbitizing does not affect this film, and on breaking the specimen exhibits flakes. Thus the authors recommend that tender forgings be heated no higher than the solidus at eutectoid composition, or 1220 deg. C.

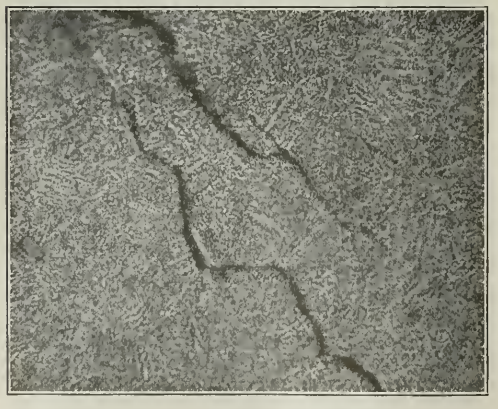

FIG. 5. FLAKES IN HEAT TREATED NICKEL-STEEL FORGING. × 500

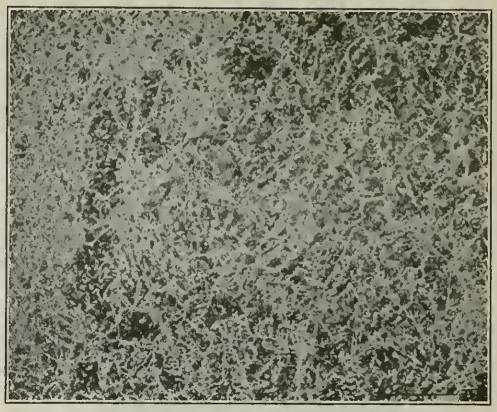

FIG. 6. IMPROPERLY FORGED BAR. × 6

Are Flakes Formed During Solidification?

Dr. H. M. Howe took issue with this theory, which in effect is that the previously solid metal developed, on pulling, a flake at segregated iron, phosphorus or sulphur spots. He supported the idea that the flake is the result of an old unwelded internal crack, deformed somewhat in forging, which opens up and becomes visible upon straining. Clayton's theory does not account for the fact that flakes are habitually ranged in a diagonal direction in square ingots, one-third the way from outside to center, and in a tangential direction in round or octagon ingots. Now if flakes were due to burning during reheating, they should occur in the outer portion of the ingot where it is hottest, assuming that the impurities which cause low-melting spots are not localized during solidification. Furthermore, flakes appear in steel whose heat treatment has never exceeded 900 deg. C.

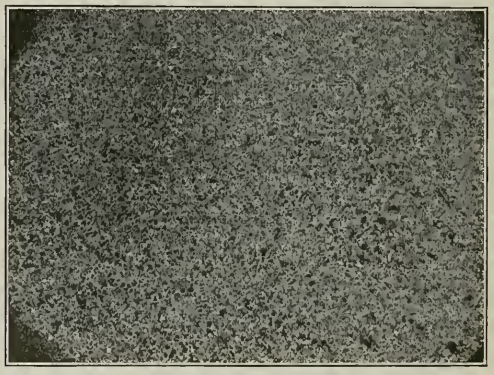

FIG. 7. PROPERLY FORGED BAR. × 6

Flakes are notoriously connected with tender steel, of the chromium, chromium-nickel, nickel, or chromium-

carbon varieties. Naturally, then, flaking disappeared in certain alloys as the nickel was reduced, and this composition was then found to be amply good for many uses. Again, killing the steel in the furnace increases its compactness, and therefore its tenderness; consequently this metallurgical practice caused more flakes. If such be the case, sound practice demands that this tender steel be humored and so cast that cooling stresses be not excessive; in other words use round molds, strip as soon as the walls are strong, and cool at an intermediate rate by burying in ashes. This lessens the number of flakes enormously, although it should increase the interdentritic segregation.

When Flaking Should Occur

There are three tender stages in the manufacture of a piece of metal, and flaking should occur at one of them. First in the mushy stage of early solidification, the outer walls of the ingot may crack and the fusible portion bleed. This should leave flakes with dendritic sides, as is shown in blow holes or pipes. But this is not their condition, and probably flakes are not formed so early. Second, at a blue heat, moderately below recalescence. Now the outer shell is contracting, while an inner lining just at the recalescent point expands suddenly, throwing large tension stresses into outer metal. The common occurrence one-third the way to the center also suggests that this is the most likely origin. A final tender stage in the history of a piece is when quenching the finished forging. Failure at this point, however, produces the well-known hardening cracks, which are flat breaks, with no white spots; fine crystalline because fine grained.

Hence Howe agrees with Rawdon in his contention that flakes originate in the ingots of tender alloy steels as intercrystalline shrinkage cracks, probably intensified by inclusions and segregations. They persist throughout forging, not being welded, and on straining, reappear with bright surfaces representing the deformed surface configuration of the original crystals. They can consequently be controlled by careful casting, soaking, reheating and heat-treating practice.

Prize Essay Contest in Industrial Economics

The National Industrial Conference Board announces a prize of $1000 for the best monograph on any one of the following subjects:

1. A practicable plan for representation of workers in determining conditions of work and for prevention of industrial disputes.
2. The major causes of unemployment and how to minimize them.
3. How can efficiency of workers be so increased as to make high wage rates economically practicable?
4. Should the State interfere in the determining of wage rates?
5. Should rates of wages be definitely based on the cost of living?
6. How can present systems of wage payments be so perfected and supplemented as to be most conducive to individual efficiency and to the contentment of workers?
7. The closed union shop versus the open shop; their social and economic value compared.
8. Should trade unions and employers' associations be made legally responsible?

Full details concerning the contest can be secured by addressing Magnus W. Alexander, managing director, 15 Beacon St., Boston, Mass.

Import and Export Statistics

The bureau of foreign and domestic commerce of the United States Department of Commerce announces the following import and export figures for the month of December, 1918.

IMPORTS OF TIN BARS, BLOCKS, PIGS, ETC., BY COUNTRIES AND DISTRCTS

Countries	Lb.	Value	Districts	Lb.	Value
England	179,662	$133,116	New York	768,973	$620,051

Linseed Production in Argentina

During the war enormous quantities of linseed were required to produce the oil for ship paint, camouflage material and rainproof equipment. Argentina, possessing the largest linseed area of any country, played an important part in supplying this demand. About 3,000,000 acres are devoted to linseed, while the corresponding area in the U. S. is only 2,000,000 acres.

The official estimate of the 1919 crop gives the total production as 705,000 tons, the exportable surplus being estimated at 679,000 tons, or about 29,000,000 bushels. During 1918, the United States received practically two-thirds of all the linseed exported from Argentina. On Dec. 5, 1918, the War Trade Board issued a ruling (W.T.B.R. 376) modifying the restrictions which had been placed upon the importation of linseed in July, 1918, to permit the licensing of imports from the River Plate districts (Argentina and Uruguay) of not to exceed 15,000 tons (635,000 bushels) for each of the months of January, February, March and April, 1919, allocation to be made by the War Trade Board.

The linseed requirements of the United States for the 1918-19 fiscal year were given as 26,000,000 bushels.[1] The supply from the American Northwest is given in the January official estimate as 14,657,000 bushels. This means that more than 11,000,000 bushels must be obtained from Canada, India and Argentina.

One of the most interesting developments in the attempt to increase the domestic utilization of the linseed crop has been the discovery that linseed straw is the most practical material for the production of grain bags. The shortage of warehouse space has made imperative the use of large numbers of bags for storing the wheat crops. A domestic source of supply has apparently been found in the 5,000,000 tons of linseed straw available annually, since experiments with the fiber indicate that it is suitable for the manufacture of bagging and binder twine also.

Important Meetings of Chemists and Electrochemists

The American Chemical Society will hold a "Victory Meeting" at Buffalo April 7 to 11. Tentative plans for the program include special consideration of the protection of American chemical industries and the necessary legislative action to secure such protection. Arrangements are being made for visits to plants of important Buffalo manufacturers and for a comprehensive view of the chemical industries of Buffalo and Niagara Falls. Headquarters will be at the Hotel Statler and sectional meetings will be held at the Technical High School.

The American Electrochemical Society will hold its annual meeting in New York April 3 to 5. The feature of this meeting will be a symposium on released information regarding war work. The censorship on scientific information which was enforced during the war has been largely raised and as a consequence it is anticipated that a great deal of valuable information can now be released. The sessions will be held in Rumford Hall, the Chemists' Club.

[1]Report of Linseed Oil Committee of the National Paint, Oil and Varnish Association at the convention held in Boston Dec. 2-4, 1918.

Industrial Use and Limitations of Respirators, Gas Masks and Oxygen Breathing Apparatus

DURING the last year the Bureau of Mines, Department of Interior, has received many inquiries regarding the use of Army gas masks in the industries for protection against poisonous and irritating gases. These inquiries show a general belief on the part of the public that this type of mask will protect the wearer under all conditions against any gas whatsoever, even in absolutely irrespirable air to the exclusion of the more cumbersome mine rescue breathing apparatus. This erroneous belief will no doubt be further confirmed by millions of discharged soldiers who have been trained in the use of the gas mask and have been taught that it gives them absolute protection against all gases used in warfare or likely to be used. These men will not realize that out in the open air of the battlefield the percentage of gas in the air can never be anywhere near as large as may occur in the confined spaces of a factory operation. A mask may afford complete protection under outdoor conditions and break down at once when used indoors where a gas container has burst and filled the room with a greater concentration of gas. It must also be remembered that the absorbents in the Army respirator, which filter out the poisonous gas, are specially designed for the gases used in warfare, and as a matter of fact do not protect against the more common industrial gases as, for example, illuminating, natural, producer and blast furnace gas.

The Army gas mask never should be used in mines, because of the uncertainty there is of the kinds and amounts of gases in the atmosphere and liability of insufficient ogygen to support life.

In view of these limitations of the Army gas mask, which, if not realized, will lead to serious accidents and fatalities, the Bureau of Mines is issuing this brief statement of the industrial use and limitations of the several dust respirators, gas masks and ogygen breathing apparatus.

Dust Respirators

Protection from dust and liquid mists is obtained by the use of a simple dust respirator, which removes these particles by means of a filter of moist sponge, cotton or wool pad, porous paper or even a very fine mesh metallic gauze. The respirator may enclose the mouth and nose only, or it may be combined with a face mask containing eye pieces if the eye must also be protected. The simple "pig snout" respirator containing a moist sponge has been on the market for years. It is highly uncomfortable to wear, rather insufficient for removing fine dust, and most workmen perfer to tie a large handkerchief over their nose and mouth. Some improvement has been made in recent years, but on the whole a really efficient and comfortable dust respirator that workmen will wear continuously is yet to be devised. On account of the urgent need of such a device for safeguarding the health of workmen in the mining and metallurgical industries, the Bureau of Mines has undertaken a study of dust respirators with a view to obtaining as satisfactory a model as possible.

The Army gas mask consists of a face piece of rubber and cloth fabric, containing eye pieces and connected by means of a flexible rubber tube to a canister containing charcoal and soda-lime for filtering out the poisonous gas from the inhaled air. The canister is supported in a knapsack slung from the neck.

The Army gas mask is by no means the unusual protective appliance that it is popularly believed. It does not afford universal protection against all gases, nor can it ever be used safely in low oxygen atmospheres. It furnishes no oxygen to the wearer and can only remove comparatively small percentages of poisonous gas from inhaled air, usually less than 1 or 2 per cent. Higher percentages will immediately penetrate the canister and "gas" the wearer. The standard Army gas mask will furnish protection against percentages not exceeding 2 per cent of the following gases in air: Sulphur dioxide, hydrogen sulphide, chlorine, carbon bisulphide, nitrogen peroxide, aniline vapor, benzyl bromide, benzyl chloride, chloracetone, chlorpicrin, hydrogen chloride, phosgene, sulphur chlorides, xylyl bromide, stannic chloride, titanium tetrachloride and silicon tetrachloride.

It will be seen from the above that the field of usefulness of the Army mask is confined to certain of the chemical industries, around smelters and roasters where sulphur fumes are given off and in the industries using chlorine and bleaching powder. The Army canister also contains cotton filter pads which remove irritating and poisonous dusts, which increases its usefulness around smelters where sulphur and arsenic fumes must be removed.

The Army mask furnishes no protection whatever against carbon monoxide. This is the poisonous constituent of blast furnace, producer and illuminating gases, and of mine gases after fires and explosions in coal mines. Carbon monoxide is also likely to be present in ordinary fire-fighting conditions met by fire departments. Moreover, in all of these cases there is likely to be a deficiency of oxygen. Therefore, for adequate protection against these conditions the oxygen breathing apparatus must be used, and reliance on the Army mask may be fatal.

Ammonia is another gas that will penetrate the standard Army canister. However, a special chemical may be placed in the Army canister which will adapt it for use around refrigerating plants.

Oxygen Breathing Apparatus

The self-contained oxygen breathing apparatus can never be displaced by the gas mask for use in atmospheres deficient in oxygen. Such atmospheres are encountered in mine rescue work, in gas mains, blast furnace stoves, gasoline tanks, etc. Aside from the lack of oxygen, carbon monoxide is also present, for protection against which the Army mask is useless.

The oxygen breathing apparatus must also be used instead of the Army gas mask wherever there are large quantities of irrespirable or poisonous gases, as for example, in entering a gasoline tank containing some residual liquid, or similar tanks, towers and other closed spaces. The concentration of vapors produced by volatile liquids in closed containers is too high to be entirely removed by gas mask absorbents. The only recourse in such cases is a self-contained appliance in which the wearer does not breathe any of the irrespirable atmosphere.

Importance of Taking Expert Advice

Owing to the many factors entering into the use of protective respiratory appliances, the importance of competent advice on the selection and use of such appliances cannot be overestimated. The fact that the Army and Navy used gas masks has been widely disseminated and its significance is likely to be misunderstood, especially by men who have had some training in their use. It also should be made known that both the Army and Navy used the oxygen breathing apparatus in its appropriate place.

In connection with the Bureau of Mines work of safeguarding the health of miners and workmen in the metallurgical industries, a general investigation of respirators, gas masks and breathing appliances is being undertaken at the Pittsburgh Experiment Station of the Bureau. This research will be conducted by experienced chemists and engineers who had charge of gas mask research in the Bureau's war gas investigations and subsequently in the Research Division of the Chemical Warfare Service, U. S. A.

Pittsburgh Experiment Station,
Bureau of Mines.

Summary of the Tin Situation by the Geological Survey

The tin situation in this country continues inactive and unsettled, caused mainly by the large stocks in the hands of the Government and of large consumers, and the restrictions on imports, except ore purchases by domestic smelters. In order to stabilize the erratic market which was so prevalent during the first half of 1918, announcement was made in September of the inter-Allied control. By this arrangement, buying in the primary markets was done by Government agencies, and no tin could be imported into the country except through the United States Steel Products Co. From the inter-Allied purchases there was allocated to the United States about 10,000 tons, at a price approximately 72½c. per pound f.o.b. Eastern points.

The signing of the armistice found the Steel Products Co. with practically the entire allocation on hand, besides large stocks in the hands of the principal consumers. Until these stocks are absorbed and restrictions removed from importation, the tin situation is likely to remain uncertain. How long it will take to absorb these stocks will depend mainly on the condition of business and the production of the domestic smelters, which are in an advantageous position, inasmuch as they can purchase their ores in an open market at considerably below the fixed price of tin in this country. They are in a position, therefore, to sell their product at a few cents under the fixed price, giving them the control of the market and at the same time insuring large profits.

It is estimated that the consumption of tin will be largely curtailed during 1919, and probably will not exceed 3500 tons per month. It is thought the requirements can be easily supplied by domestic smelters using foreign ores, supplemented by the stocks now on hand.

Concrete as a Chemical Engineering Material*

By Maximilian Toch

IT may truly be said that this is the age of concrete. What progress would our new factories have made after this country went into the war, when steel and iron were unobtainable, had it not been for the ability to use portland cement in its place? It is no criticism to say that portland cement concrete is an unfinished material when used in the erection of chemical works. No floor in any factory will last very long made of portland cement and sand, unless it is treated in some manner. I have seen instances where the concrete foundations of vinegar tanks were decomposed until they resembled a material like cheese, owing to the solvent action of acetic acid. I have seen foundations of motors and machinery where the oil drippings disintegrated concrete in a relatively short period. I could cite many more cases, but these will suffice. There are a great many materials which preserve portland cement construction against acids, alkalis, oil and saline solutions, and there is no one material which may be regarded as a panacea for all the defects of concrete. When the defects of concrete are mentioned I must again impress upon you that I am not criticising the material; but a concrete sidewalk is about the only cement construction of any magnitude that I can recall which needs no treatment to make it waterproof, wearproof and weatherproof.

Defects of Concrete Construction

Take the case of a concrete floor in a room where there is delicate machinery. In a short time the particles of sand and broken stone which form the composite of the concrete became loosened, float around in the air and lodge on the contact points of this delicate machinery. Take the case of foundations in chemical works, where acids and alkalis drip on the foundations. Take the case of concrete foundations of factory buildings on a waterfront, where niter cake and sludge acids are discharged in the stream, and you will soon erode the concrete foundations. All this is due to a very simple chemical problem. Portland cement has been described so often that I do not need to go into its chemical composition other than to say that when it is mixed with water it generates lime and the lime forms a glutinant material which binds the particles together. This same condition is identical in all mortars, and the common, ordinary lime mortar of building material, while it contains a much greater amount of lime than portland cement, is weaker in every respect than portland cement itself. Lime is slightly soluble in plain water and is relatively more soluble in salt water. This accounts for the disintegration of portland cement at the seashore. Any acid, no matter how weak, forms a chemical combination with lime; when the lime is attacked in portland cement the structure crumbles.

There are a large number of methods used for the protection and preservation of portland cement; and, as I have said before, there is no single method applicable in every case. Our Government and every other Government have had an enormous amount of trouble in building dry docks which would withstand sea water, even though some of these dry docks were faced with granite or other building stones, because the building stones must be cemented together with a mortar containing lime in some form. A very interesting case developed in one of the large dry docks in New York Harbor, where the sea walls were waterproofed with an integral material but where the bottom was not waterproofed, and after a lapse of five years the solvent action of the salt water attacked the bottom, but left the sides untouched. But the greatest problem of all is the construction of foundations, vats and storage buildings for chemical materials which should be proof against acids and alkalis under normal conditions. Up to within two years ago no one ever thought of building storage warehouses of concrete for the storing of large quantities of niter cake. This material, as you know, is an acid sulphate of sodium containing as high as 30 per cent. of free sulphuric acid, and yet it has been possible to build successfully such a storage building which would house niter cake and not attack the walls and floors made of concrete. In a case like this, it is necessary to use two methods—one, an integral method, and in addition to this, a surface coating which will be acidproof.

Concrete Tanks for Storage of Oil

The great scarcity of boiler plates for the building of large tanks forced our own Government to build tanks for the storage of fuel oil, of concrete; and, as there are two kinds of fuel oil—the very heavy Maltha, of the West Coast, and the thinner type of Pennsylvania and Ohio—it soon becomes obvious that the Maltha or Western type could be stored in any kind of a pit made of any material, but the Eastern oil would soon destroy the crystalline structure of portland cement and leak through. So it became essential to find methods of making concrete oilproof, and in this again the integral plus the surface coating method are essential.

To use a very homely comparison, and one that is somewhat graphic, I must frankly state that unless the engineers' specifications are strictly carried out, failure will inevitably result and no material should be blamed for a lack of supervision. To write a specification for concrete and chemical engineering construction is not an easy matter, and unless the inspector is intelligent and watchful, failure may result. I always think, in this connection, of the case of the man who went into a restaurant and called the waiter, and explained to him the kind of a steak that he wanted. He insisted that the steak should be an inch and a half thick and six or seven inches long, and it should be grilled over a coke fire for forty-five minutes at a distance of one foot from the fire; that after it was grilled it should be smothered with mushrooms and onions and then allowed to seep for ten minutes and placed on a hot plate and served to him. The waiter, after having carefully listened to these orders, walks over to the kitchen and yells "One steak." This is a very fair example of how many specifications are carried out and how engineering materials are blamed for the lack of carrying out the orders carefully.

*Address delivered before the American Institute of Chemical Engineers, Chicago, Jan. 16, 1919.

It is not my purpose to give any specifications for the various types of waterproof and chemicalproof materials now on the market for the preservation of portland cement concrete; but suffice it to say that there are not very many materials on the market which are completely meritorious, and the negative attitude in times gone by of the Bureau of Standards is to my mind largely due to the fact that several materials have been exploited which have been without merit. In fact, unless a man is scientifically trained and knows the reactions that may take place when various materials are subsequently stored or come in contact with concrete, he cannot devise a material which shall fulfill the purpose, but fortunately, as these materials are found out and found wanting, they from time to time disappear from the market, but in the meantime they harm directly and indirectly those compounds which have shown and proven their efficacy. I have a case in mind where one of the foremost architects in the United States has condemned all materials on account of failures which he has seen made with materials which should not have been used.

Types of Waterproofing Used in Chemical Industries

The following, in a general way, are the types of waterproofing used in the chemical industries:

First—The integral type, which is used in the form of a dry powder, and the action is to densify the concrete, give it colloidal properties and to lubricate the mass while pouring. There are a large number of paste aqueous materials on the market, some of which are a kind of soap. Generally speaking, these soaps are to be avoided.

Second—The next type well known is the varnish type, which depends for its reaction on acid resins and has proved itself waterproof, oilproof and wearproof.

Third—The third type is the fluo-silicate type, which in conjunction with the acid resin type or the bituminous coating type, where a proper bond can be effected, has given most excellent results.

There are, of course, modifications of these types, and I have in mind the building of the first storage building for niter cake large enough to hold a thousand tons, in which the concrete, after two years, has not shown the slightest disintegration. Another modification of this type is used for the building of concrete foundations along waterfronts where the water is decidedly acid and it is quite obvious that unless the concrete is properly treated the solvent action of acid water would erode and dissolve away the concrete in a short time, and yet under proper treatment such foundations have stood up without showing the slightest sign of decay or disintegration, and the manufacturers are all aware of the fact that concrete may be constructed which is proof against acid fumes, and a number of these buildings are all in successful operation.

We must bear in mind that civilization is the great destroyer of our building materials. In the balmy air of southern Italy, where temperature changes are not very great and where the people still burn wood, and very little of that, and that only for domestic purposes, the masonry construction of the Roman Aqueduct has stood for two thousand years without disintegration. The same is true of the masonry construction of Egypt, yet we know that our obelisk, after having stood for twenty centuries in Egypt, began to disintegrate after it was erected in Central Park in New York, due first, to the climatic changes, and secondly, to the sulphuric acid in the air. I had occasion to examine most minutely the Tomb of Perneb after it arrived and was set up at the Metropolitan Museum of Art in New York. This tomb was built 4500 years ago, and the stones were in perfect condition when they arrived, but the atmosphere in New York soon began to produce an excrescence, due entirely to the foreign substances in our atmosphere. The same is true of the monumental buildings of London, where, as long as there were no factories, the great buildings showed no signs of decay, but when London began to burn soft coal and belched sulphurous and sulphuric acid into the air, the building stone and cement construction immediately showed signs of decay and deterioration. This condition is of course amplified by the ordinary fumes in a chemical factory itself, and it is very fortunate that through modern methods of skillful investigation portland cement can be made to resist these conditions. Railway engineers are recognizing this all over the country, and where locomotive blasts belch forth their fumes against concrete bridge arches, the arches are treated so that they will withstand the onslaught of chemical vapors.

Methods of Protection

Briefly summed up, the methods for the protection of concrete against erosion, chemical action, disintegration and decomposition are as follows:

First—The well-known membrane method, which consists, usually, of applying tar, asphalt or other bituminous materials, in conjunction with a membrane such as felt, burlap or textile fabric of any kind;

Second—The brush application on the exterior of a concrete construction of a hydrocarbon material which is neutral;

Third—The brush application of an acid resin which combines with the lime of the concrete and forms an integral material on the surface only;

Fourth—The addition of a dry powder not to exceed 2 per cent, to densify concrete and to make it waterproof;

Fifth—The addition of an integral powder to the concrete, to make it acidproof and alkaliproof;

Sixth—The application of a brush coating or spray of a silicofluoride, which precipitates silica into the interstices or pores of the concrete and makes it proof against oil and water;

Seventh—Coating the concrete structure with two solutions which interact and precipitate and form an insoluble residue which prevents penetration of chemical compounds.

This, in a general way, is the practice of the present day, and sometimes two or more methods are used where the concrete is subjected to extraordinary conditions, but sufficient work has been done on this subject to enable chemical engineers to state with a considerable degree of assurance that concrete, which ten years ago was regarded as unfit as a building material in the chemical industry, can to-day be so manipulated that it has taken its place as one of the best, if not the cheapest, and most enduring material in chemical engineering.

Milling Calculations

A Compilation of Formulas Useful in Determining Extraction of Processes, Efficiency of Machines, Density of Solids, Solutions and Pulps—Notes on Methods of Testing and Microscopic Examination

By ROBERT S. LEWIS*

IN ORDER to exercise proper control over the operation of milling plants it is necessary to make frequent and regular calculations of mill performance. The extraction made by the plant, by the individual machine or group of machines, and the tonnage treated are the items that most commonly require determination, and these are computed by means of weights and assays. Efficient and economic operation demands that concentrating machines be operated at full capacity and with a uniform rate of feed, but such conditions are seldom if ever attained in practice. As soon as a mill goes into operation the usual tendency is to crowd through it as large a tonnage as possible. Many a plant is handling an overload of from 50 to 100 per cent, if the capacity for which the mill was originally designed is taken as a basis of calculation. It is impossible to prevent choke-ups in pipes and launders, belts jumping off, or the breaking of machine parts. These result in sudden stoppages of feed, and, even though promptly remedied, prevent the maintenance of smooth operating conditions.

Computation of Extraction

Skilled as some operators become in judging the performance of a machine, the actual work that it is doing cannot be learned without making tests. For plants using straight mechanical concentration, the calculation of extraction deals with only three quantities: feed or heading, tailing and concentrate. Where the weights and assays of these items are known, the calculation of extraction is quite simple. For plants using a more complicated process, such as concentration followed by the cyaniding of sands and slimes, the computation of extraction becomes longer. The difficulty of correctly sampling certain mill feeds, such as those containing native gold or native silver, is often urged as a sufficient reason for using the method where extraction is based upon the metal recovered and the loss in the tailing. Instead of using the formula

$$\text{Extraction} = \frac{\text{Metal in concentrate}}{\text{Metal in ore}}$$

it is considered that

$$\text{Extraction} = \frac{\text{Metal in concentrate}}{\text{Metal in concentrate} + \text{loss in tailing}}$$

This latter method may be satisfactory from the viewpoint that the operator is concerned not so much with what is in the ore as with what he recovers and what he loses. However, such a calculation does not show the losses that may take place in the various stages of operation, for example, the wasting of valuable solutions and the loss by dusting or through fume and smoke in smelting plants. All quantity estimates are based on dry ore, yet the latter formula would not indicate that a serious error in moisture determination was being made.

Consider the case of a copper concentrator handling 10,000 tons of ore per day. This is reported as dry weight, but suppose an error in moisture determination has been made so that this weight really contains 0.5 per cent of water. Then 50 tons of water is daily reported as ore. This amounts to 1,500 tons at the end of a month and if the ore assays 2 per cent copper, the discrepancy between the amount of copper calculated as coming to the mill and that actually contained in the ore is 60,000 lb. per month. This copper has apparently been lost in the mill, since the copper actually in the concentrate together with that lost in the tailing fails to check the copper in the feed by this amount.

Formulas Disregarding Middlings

It is not convenient or always possible to segregate and weigh the concentrate produced each day, but its weight can be calculated, as will be shown below.

Let H = weight of feed. (Generally in dry tons of 2000 lb.)
T = weight of tailing.
C = weight of concentrate.
h = assay of feed.
t = assay of tailing.
c = assay of concentrate.

As the whole is equal to the sum of its parts, we may write

$Hh = Tt + Cc$ and $H = T + C$. Eliminating T,
$Hh = t\,(H - C) + Cc$ or
$H\,(h - t) = C\,(c - t)$, whence

$$(1) \qquad \frac{H}{C} = \frac{c - t}{h - t} = R$$

R is called the ratio of concentration and signifies the number of tons of feed required to yield one ton of concentrate. When this figure has been determined for an ore, it is a simple matter to calculate how much concentrate will be obtained from a given tonnage of ore or what tonnage of ore should be put through the mill to yield a desired weight of concentrate. Thus $H = CR$, or $C = H/R$.

The extraction E is the percentage of total mineral in the ore that is obtained in the concentrate. Obviously $E = Cc/Hh$, but this has the disadvantage of requiring weights as well as assays for its solution. By combining this formula with formula (1) for the ratio of concentration we may write

$$(2) \qquad E = \frac{Cc}{Hh} = \frac{c}{Rh} = \frac{c(h - t)}{h(c - t)}$$

In this formula all weights are eliminated.

*Professor of mining, University of Utah.

Example: The assays from a copper concentrator are as follows:

Feed	1.6 per cent Cu.
Tailing	0.6 per cent Cu.
Concentrate	16.0 per cent Cu.

Then $E = \frac{16(1.6 - 0.6)}{1.6(16 - 0.6)} = 0.65$, or the extraction is 65 per cent.

When the weights of the feed and tailing or the concentrate and tailing are known, we may write

$$(3) \qquad E = \frac{Cc}{Cc + Tt} = \frac{Hh - Tt}{Hh}$$

Formulas Involving Middlings

In case a middling product is made and must be taken into account, the formulas become more complicated and it is necessary to use both weights and assays[1].

Let M = weight of middling and m = its assay, then, using the same notation as before,

$$(4) \quad E = \frac{Cc}{Hh} = \frac{Cc}{Tt + Cc + Mm} = \frac{Cc(h - t)}{hC(c - t) + Mh(m - t)}$$

$$(5) \quad T = \frac{C(c - h) + M(m - h)}{(h - t)}$$

$$(6) \quad H = \frac{C(c - t) + M(m - t)}{(h - t)}$$

In some cases the interpretation of small scale gravity concentration and flotation tests is rendered ambiguous by a middling product, which would be eliminated in regular operation by being returned to the head of the machine[2]. The value of the clean concentrate and tailing produced would not be affected by the return of this middling. Such an assumption seems justifiable on the ground that the middling is of the same materials as the ore, being merely a mixture of the same constituents found separately in the concentrate and tailing.

An Illustration

Suppose a 10-lb. sample of gold ore assaying 0.895 oz. is concentrated with the following results:

1.15 lb.	middling assaying	0.35 oz.
1.25 lb.	concentrate assaying	6.53 oz.
7.60 lb.	tailing assaying	0.055 oz.

It is desired to calculate the weights of the products and the extraction with the middling eliminated. If R by formula (1) gives the tons of ore required to make 1 ton of concentrate, 1/R is the fraction of a ton of concentrate made from one ton of ore. Inverting formula (1) and substituting the above assays gives

$$\frac{1}{R} = \frac{0.895 - 0.055}{6.53 - 0.055} = \frac{0.840}{6.475} = 0.1297$$

As the assays of the concentrate and tailing remain the same, the total weight of concentrate produced would be $10 \times 0.1297 = 1.3$ lb., and of the tailing $10 - 1.3 = 8.7$ lb. We now have for a sample of 10 lb. of assay 0.895 oz., a concentrate of 1.3 lb., assay 6.53 oz., and a tailing of 8.7 lb., assay 0.055 oz. The extraction can now be calculated by formula (2).

Consider the following flotation test: 500 g. of ore is treated in a test machine for fifteen minutes, the products being a final tailing and a rough concentrate. This concentrate is re-run, giving a finished concentrate and a middling, which is too valuable to run to waste. In practice the middling is returned to the head machine. The data from the test are tabulated below:

	Weight Grams	Assay Per Cent Pb
Feed or heads	500	5 7
Concentrate	31 5	41 0
Tailing	470 0	2 1
Middling	48 5	13 94

From (2) the extraction is $\frac{41(5.7 - 2.1)}{5.7(41 - 2.1)} = 0.666$ = 66.6 per cent.

The relative weight of concentrate, the middling being eliminated, is found from formula (1), inverted, as $\frac{5.7 - 2.1}{41 - 2.1} = 0.0926$, and the total weight is 500 g. $\times$ 0.0926 = 46.3 g.

Where the extraction is calculated from assays, as indicated above, the result is called the "apparent" recovery and is not the "actual" recovery based upon the weights of the ore and concentrate. The discrepancy between the two recoveries is due to errors in sampling and assaying. The above formulas are to be relied upon only in so far as the sampling and assaying are correct. While it is not the purpose of this article to discuss the effect of incorrect assays, the bibliography gives some references to that question.[11,12]

Calculations in Cyanide Practice

In cyanide plants the calculation of extraction is complicated by the number of items that must be considered. For a plant using gravity concentration followed by cyaniding of the sand and slime, the extraction by each treatment can be figured separately and all can be combined into one result. If the extraction by concentration is 30 per cent and an extraction of 75 per cent is made on the 70 per cent of the total mill feed that goes to the cyanide plant, the extraction for the whole mill is 30 per cent + (75 per cent $\times$ 70 per cent) = 30 per cent + 52.5 per cent = 82.5 per cent.

A formula for calculating the extraction where combined processes are used is given below[3].

Let E = per cent extraction;
h = assay of feed; H its weight;
m = assay of concentrate tailing; M its weight;
c = assay of concentrate; C its weight;
d = assay of sand head; D its weight;
f = assay of slime head; F its weight;
d_t = assay of sand tailing; D_t its weight;
f_t = assay of slime tailing; F_t its weight.

Then, $H = C + M$;
$M = D + F$;
$Hh = Cc + Mm$;
$Mm = Dd + Ff$;

$$E = \frac{Cc + D(d - d_t) + F(f - f)}{Hh}$$

To eliminate all weight factors, eliminate M from the first and third equations just above:

$$\frac{C}{H} = \frac{h - m}{c - m}$$

Eliminate C from the same two and F from the second and fourth:

$$\frac{M}{H} = \frac{c - h}{c - m}$$

$$\frac{D}{M} = \frac{m - f}{d - f}$$

Multiplying these two gives

$$\frac{D}{H} = \frac{(c-h)(m-f)}{(c-m)(d-f)}$$

Derive similarly the relation

$$\frac{F}{H} = \frac{(c-h)(m-d)}{(c-m)(f-d)}$$

and substitute the appropriate ratios in the expression for E:

$$(7) \quad Eh = \frac{c(h-m)}{(c-m)} + \frac{(c-h)(m-f)}{(c-m)(d-f)}\left(d - d_t\right) + \frac{(c-h)(m-d)}{(c-m)(f-d)}\left(f - f_t\right)$$

It should be noticed that the formula is the summation of the three extractions made separately by concentration, by sand treatment and by slime treatment.

Equation (7) may be simplified somewhat into the form

$$E = \frac{c(h-m) + \frac{c-h}{d-f}[(m-f)(d-d_t) - (m-d)(f-f_t)]}{h(c-m)}$$

At plants where the continuous counter current decantation process is followed the formulas for computing the extraction depend upon the details of the treatment used. An excellent discussion of this subject is to be found in the trade publication of the Dorr Company of Denver entitled "Continuous Counter Current Decantation."[12a and 30]

Screening Practice

Screening tests are a valuable means of controlling some details of milling operations, but, if due care is not exercised in making the tests and if the results are not correctly interpreted, the information obtained may be very misleading.[47] In order to make informing comparisons of screen tests three requirements should be fulfilled.

1. Screens of the same size of aperture and wire should be used for each test.

2. The same method of screening should be followed in all tests.

3. All tests should be run for the same length of time, and preferably in a mechanically operated screening machine.

The word "mesh," meaning the number of openings per linear inch of screen, has no definite meaning. Obviously, the number of openings per linear inch may remain the same for various screens, each of which is made of wire of a different diameter from that of the others, and yet no two screens would have the same aperture. The importance of using a standard series of screens for testing purposes cannot be too strongly urged, for without such a uniformity of screens, published data of tests are rendered worthless. Screen manufacturers have discussed this matter and a set of standard screens has been recommended.[48] This series is based on a 1-mm. opening with the square root of 2, or 1.4142, as the ratio of the openings of successive sieves coarser than 1 mm., and the fourth root of 2, or 1.1892, as the ratio of the openings of successive sieves finer than 1 mm.

Three methods of screening, with some slight variations, are in common use. They are dry screening, wet screening and what may be called a combination method. For dry screening the desired screens are nested in proper order, the sample to be tested is placed on the top or coarsest screen and the set is shaken for a certain length of time. In wet screening the sample is washed through each screen either by means of a jet of water or else in a vessel of water, the respective sizes remaining on the different screens dried and weighed. This is the most accurate method of screening, but much time is required for making a test. In the combination method, the whole sample is first washed on the finest screen used and both oversize and undersize dried. The oversize is then treated as in dry screening, the material passing the finest screen is added to the undersize made by the washing to obtain the final result. This method saves time as against the wet test and is sufficiently accurate for most purposes. All tests should be continued for the same length of time, usually from 10 to 20 minutes; the most suitable time for any particular ore is found by experiment. During any test some material will continue to pass through the screens, though the shaking is maintained for hours. When working on the screening of cement, the United States Bureau of Standards stops a test when the material passing the screen in a given length of time reaches a certain minimum amount.

For ores that have a tendency to fracture into long prisms or needles violent shaking of the screens may cause many particles to pass through a screen, while a gentle screening of the same ore would give a different result. The finest particles of ore tend to stick on the surface of the larger particles and also to adhere to the wires of the screens. Sometimes this fine material forms into balls and remains on the coarser screens. Wet screening is, therefore, more accurate than dry screening. Shaking in a machine eliminates the personal equation, and thus makes it possible to compare different tests satisfactorily. Duplicate tests on the same material should give practically identical results. Since hand screening necessitates the use of only one screen at a time and a screening machine will take the entire set of screens at one time, machine screening becomes imperative where a large number of tests must be made daily.

The results of screening tests are, at best, only approximations of the truth, but that is all the more reason why the greatest care should be exercised when making them. Screen apertures grow larger as the wires wear; evidently, a badly worn set of screens will not give the same results as a new set. In reporting the results, the various sizes should be tabulated and a curve should be plotted from the data thus obtained.

Screen Efficiency

It is possible to make fairly reliable comparisons of the work done by different crushing or grinding machines by means of screening tests. However, it should be remembered that a single test may be quite unreliable as a basis for judging the performance of a machine. Thus, in checking up the work of a ball or tube mill, the average of a number of tests extending over a long period of time, several months or even a year, is the only reliable indicator of the work that the machine is doing.

In a mill where the crushed ore is separated into various sizes by screens, it may be desirable to conduct tests between different kinds of screens or it may be

necessary to determine how much additional feed a certain screen can handle without seriously diminishing its efficiency. The actual amount of screen undersize in the feed must be determined by careful laboratory screening tests. Call this the "actual undersize." Then run a known quantity of feed through the screen and weigh the undersize produced, calling this the "apparent undersize. Then the efficiency of the screen is the apparent undersize divided by the actual undersize.

A test run on 50 tons of feed gave 10 tons, or 20 per cent, as the apparent undersize. A screening test indicated that the feed contained 30 per cent actual undersize. The efficiency of the screen was, therefore, 0.20 ÷ 0.30 = 0.67, or 67 per cent.

Calculating the Efficiency

It is not always convenient to weigh large quantities of material. By the use of formula (2), the efficiency of a screen or trommel can be calculated from screening tests of the feed, oversize and undersize[4]. If f, u and o be used to represent the respective percentages of feed, undersize and oversize that go through the given mesh, we may write

$$E = \frac{u(f - o)}{f(u - o)} \tag{8}$$

In the above example, screen tests showed that the oversize from the screen contained 12.5 per cent of material that should have passed through the screen, and that there was 30 per cent of undersize in the feed. Assuming that the percentage of undersize in the undersize was 100 per cent (no test made on this material), the efficiency of the screen is

$$E = \frac{100(30 - 12.5)}{30(100 - 12.5)} = 0.667 = 66.7 \text{ per cent.}$$

It may be of interest to know how much of the finest sizes in the feed pass the screen. If too little wash water is being used, for instance, some of the fine material will remain in the oversize. Thus, much 200-mesh material may be contained in the oversize of a 2-mm. trommel. To determine the percentage, make screen tests on the feed, oversize and undersize, using a 200-mesh screen. Then use formula (8).

Feed in Closed Circuit

Machines run in a closed circuit always have some oversize returned. This results in a building up of the quantity of material going to the machine until it may reach several times the amount of the original feed before equilibrium is established. Unless this possibility is recognized at the time of installing the machine, a serious overload may be developed. The exact value of the ultimate feed cannot, of course, be accurately estimated beforehand. Crushing tests on the ore will give some idea of the percentage of original feed that will be returned as oversize, but, as the amount of feed increases, conditions of crushing change and the percentage of oversize made does not remain constant. Assuming, however, that the percentage of oversize remains constant, the ultimate feed would be the sum of the infinite geometrical series $x + xr + xr^2 + xr^3 + \ldots = \frac{x}{1 - r}$ where x is the original feed and r is the percentage of oversize. Suppose that a test on a set of rolls indicated that 60 per cent of the feed would be returned as oversize. On a basis of 20 tons per hour the theoretical ultimate load is then $\frac{20}{1 - 60 \text{ per cent}} = \frac{20}{0.40} = 50$ tons per hour.

Split Feeds

Screen tests may be used to show how a product is being split into two parts[5]. At some concentrators, the tailing is sent to a classifier, the spigot product going to make a dam and the overflow going into the pond to be settled.

Let T = total tailing.
P = part going to the pond.
D = part going to the dam.

If a screen test is made on the tailing, say on the 100-mesh size, the respective percentages may be designated by the symbols t_{100}, d_{100} and p_{100}.

For unit weight, $D + P = 1$

Also $Dd_{100} + Pp_{100} = t_{100}$

Eliminating P we have:

$$D = \frac{t_{100} - p_{100}}{d_{100} - p_{100}} \tag{9}$$

Example: At a certain plant screen tests gave 44.4 per cent, 75.2 per cent and 3.1 per cent as the respective values for t_{100}, d_{100} and p_{100}. Substituting in (9), $D = \frac{44.4 - 3.1}{75.2 - 3.1} = 57.3$ per cent to dam, and consequently 42.7 per cent to the pond.

This formula applies equally well where one product is split into two parts or where two are combined into one, but it is reliable only when there is a wide difference between the percentages of the two parts. Thus, if p_{100} and d_{100} were equal or nearly so instead of being 75.2 and 3.1 per cent, the formula would not give correct results. However, this point is not of great importance, since, in most cases to which it would apply, there would be ample difference between the products.

Tonnage of Mills

The large capacity of modern ball and tube mills makes it difficult, if not impossible, to cut out and weigh samples of the feed and discharge. Also it is very hard to determine correctly the percentage of moisture in the pulp. Consider the case where the discharge from the stamp mill battery is screened or classified, the oversize passing to a tube mill working in closed circuit with a drag classifier. The total tube mill tonnage, including returned feed, may be found in terms of the battery discharge as follows[6 and 7]:

Let a = per cent of minus any given mesh in battery discharge.
b = per cent of minus any given mesh in tube mill feed.
c = per cent of minus any given mesh in tube mill discharge.
d = per cent of minus any given mesh in classifier overflow.
B = battery tonnage (dry)
T = tube mill tonnage (dry)

Then $aB + cT = bT + dB$, whence

$$\frac{T}{B} = \frac{d - a}{c - b} \tag{10}$$

which expresses the ratio of tube mill to battery tonnage.

Another method of computing tube mill tonnage is based upon the material in the battery discharge that

does not show in the tube mill product[5]. For example, take the following case:

DATA FROM SCREEN TESTS (CUMULATIVE)

Mesh	Battery Discharge, Per Cent	Tube Mill Feed, Per Cent	Tube Mill Product, Per Cent
10	10.3	5.4	
14	20.3	10.6	
20	30.5	15.9	
28	41.8	21.8	
35	49.5	26.7	1.0
48	56.6	33.2	4.1
65	62.2	41.3	10.6
100	68.2	61.3	30.6
150	74.8	85.7	59.2
200	78.8	93.5	71.9
−200	100.0	100.0	100.0

There is 41.8 per cent of total battery discharge which does not appear in the tube mill product. It had been determined that the mill received 62.5 tons of battery discharge per day. Then 41.8 per cent of 62.5 = 26.12 tons. But this represents 21.8 per cent of the tube mill feed. Therefore the total tube mill feed is 119.8 tons. Also 119.8 tons — 62.5 tons = 57.3 tons as the amount returned to the mill by the classifier. By formula (10)

$$\frac{T}{B} = \frac{0 - 41.8}{0 - 21.8} = 1.91.$$

Since B = 62.5, T = 62.5 × 1.91 = 119.4 tons. The same screen size, 28 mesh, is used in both cases, though any other size should give the same result by the formula if the screen tests have been accurately made.

Formulas for Pulp

The introduction of the flotation process and the methods of treatment used in cyanidation and other hydrometallurgical processes all emphasize the importance of carefully controlling the dilution of the liquid pulp. Most of the following formulas dealing with pulp calculations are from an article by W. J. Sharwood[13].

The weight of solid in a vat filled with a uniform liquid pulp can be determined by drying and weighing a known volume. By proportion, the weight of the entire volume can be calculated. If the specific gravity of the pulp and the density of the dry solid are known, the weight of dry solid per cubic foot as well as many other factors can be computed by the following formulas.

Let d = density or specific gravity of the dry solid (ore, slime or sand)

p = specific gravity of the pulp (weight of 32 cu.ft. in tons)

S = percentage by weight of dry solid in the pulp

R = water ratio of pulp (tons of water per ton of dry solid)

V = volume percentage of solid pulp (cu.ft. solids in 100 cu.ft. of pulp)

F = solid factor, or tons solid in 100 fluid tons (3,200 cu.ft.) of pulp

$k = \frac{100d}{d - 1}$, a constant for any one solid. Used to facilitate computations.

Then the total weight of pulp containing unit weight of solid is R + 1, and the volume of this amount is $R + \frac{1}{d}$, whence the specific gravity of the pulp is $p = \frac{R + 1}{R + \frac{1}{d}}$ as given in formula (12) below. Explicit

TABLE I—FORMULAS FOR WATER AND SOLID IN PULP

	Weight of Pulp	Volume of Pulp	Weight of Dry Solid	Weight of Water	Volume of Water
One ton of pulp, 2,000 lb	1 ton	$\frac{1}{p}$ fluid ton $\frac{32}{p}$ cu.ft.	$\frac{S}{100}$ ton $\frac{1}{R+1}$ ton $\frac{(p-1)k}{100p}$ ton	$\frac{d-p}{p(d-1)}$ ton	$\frac{d-p}{p(d-1)}$ fluid ton $\frac{32(d-p)}{p(d-1)}$ cu.ft.
1 fluid ton of pulp, 32 cu.ft 240 U. S. gallons 200 Imp. gallons	p tons	1 fluid ton 32 cu.ft.	$\frac{(p-1)k}{100}$ ton	$\frac{d-p}{d-1}$ ton	$\frac{d-p}{d-1}$ fluid ton $\frac{32(d-p)}{d-1}$ cu.ft.
1 cu.ft. pulp 7.5 U. S. gallons 6.25 Imp. gallons	62.5 p lb.	1 cu.ft. 0.03125 fluid ton	0.625(p−1)k lb. $\frac{(p-1)k}{3200}$ ton	$\frac{62.5(d-p)}{d-1}$ lb. $\frac{d-p}{32(d-1)}$ ton	$\frac{d-p}{d-1}$ cu.ft.
1 ton dry solid 2,000 lb	(R+1) tons $\frac{100p}{(p-1)k}$ tons	$\frac{100}{(p-1)k}$ fluid ton $\frac{3200}{(p-1)k}$ cu.ft.	1 ton	R tons $\frac{100}{S}$ − 1 ton $\frac{d-p}{d(p-1)}$ ton	32 R cu.ft. R fluid tons
1 fluid ton water, 32 cu.ft 240 U. S. gallons 200 Imp. gallons	$\frac{p(d-1)}{d-p}$ ton	$\frac{d-1}{d-p}$ fluid ton	$\frac{1}{R}$ ton $\frac{d(p-1)}{d-p}$ ton $\frac{S}{100-S}$ ton	1 ton	1 fluid ton 32 cu.ft.

One U. S. gallon of pulp = $\frac{(p-1)k}{12}$ pounds of dry solid. One Imperial gallon of pulp = $\frac{(p-1)k}{10}$ pounds of dry solid.

The relation between metric ton (1,000 kg.) and cubic meter (1,000 liters) is the same as between the ton of 2,000 lb. and the fluid ton of 32 cu.ft. One cubic meter of pulp contains 0.01 (p−1)k metric tons of solid.

functions of d and R as in formulas (11) and (14) are easily had by transposition. Formulas in S are had by substituting appropriate expressions given in (13) and (14). Also, since 100 cu.ft. pulp weighs 100 p units and contains S per cent of solid, the volume of solid in this volume of pulp is its weight divided by its density, or $V = \frac{Sp}{d}$, as shown in formula (16). Formula (15) is thus self-evident.

$$(11)\quad d = \frac{p}{1 - R(p - 1)} = \frac{Sp}{Sp - 100(p - 1)}$$

$$(12)\quad p = \frac{R + 1}{R + \frac{1}{d}} = \frac{100}{100 - \frac{S(d - 1)}{d}} = \frac{k}{k - S}$$

$$(13)\quad S = \frac{100}{R + 1} = \frac{100d(p - 1)}{p(d - 1)} = \frac{k(p - 1)}{p}$$

$$(14)\quad R = \frac{d - p}{d(p - 1)} = \frac{1 - \frac{p}{d}}{p - 1} = \frac{100 - S}{S} = \frac{100}{S} - 1 = \frac{100p}{k(p - 1)} - 1$$

$$(15)\quad F = Sp = \frac{100p}{R + 1} = \frac{100d(p - 1)}{d - 1} = k(p - 1)$$

$$(16)\quad V = \frac{F}{d} = \frac{Sp}{d} = \frac{100(p - 1)}{d - 1} = (k - 100)(p - 1)$$

$$(17)\quad \text{Fluid tons of pulp to give one ton dry solid} = \frac{100}{F} = \frac{100}{k(p - 1)} = \frac{R - 1}{p}$$

For very thin pulps, specific gravity under 1.05, S and F are practically identical, and it may be stated that S or F = k (p — 1). This is an approximation to be used for the overflow of slime settlers, spitzkasten, etc., but its limitation should always be remembered. Table I gives the above relations in a simplified manner and in a form suitable for calculation by slide rule.

Sampling Pulp

The specific gravity of pulp may be determined by several methods. The hydrometer can be used provided the pulp is not extremely thick. However, it is very difficult to keep the coarser material in the pulp from settling, and some of the pulp usually sticks to the bulb of the instrument, consequently the hydrometer usually gives results that are only approximately correct. A very satisfactory method is to use a specific gravity flask[29] made of tin in the form of a cone (Fig. 1). The bottom diameter is 6.5 in. and the side makes an angle of 60 deg. with the flat bottom. The flask should be calibrated by denting the bottom until it holds just 100cc. A tare weight which just balances the flask when it is filled with distilled water should be provided. When the flask is filled with pulp and weighed, the weights in excess of the tare weight give the decimal part of the specific gravity of the pulp. Thus, extra weights of 345 g. mean that the pulp has a specific gravity of 1.345. In general, there is no advantage to be derived from weighing closer than the nearest 5 g. or to within 0.005 of the specific gravity. A 1000-cc. graduate can be used in the same manner. Still another method is to use a bucket that holds one cubic foot of pulp. A bucket 14 in. in diameter will hold one cubic foot when filled to a depth of 11.25 in. The cubic foot point should be marked by boring a small hole through the bucket and inserting a rivet or bolt. In use, a tare weight is used to balance the empty bucket, and the weight of one cubic foot of pulp in pounds times the factor 0.016 gives the specific gravity of the pulp. A modification of this method is to mark a bucket at a point where it holds exactly 100 pounds of water. The weight of this volume of pulp in pounds gives the specific gravity directly by pointing off as decimal all figures to the right of the initial left hand figure (which is always 1).

FIG. 1. SPECIFIC GRAVITY FLASK

Care must be exercised that the sample taken is a true average of the entire volume of pulp under consideration. A small funnel or a rectangular shaped piece of tin made to slip into the neck of the specific gravity flask will enable the sampler to cut a running stream of pulp in a satisfactory manner. If the sample is to be taken from a bucket or other container, the pulp should be stirred vigorously just before taking the sample to insure that the coarser particles have not settled to the bottom of the bucket.

Density of Solids

The specific gravity of a dry solid, sand or slime is best determined by means of a weighing bottle, whose size depends upon the sensitiveness of the balance used. Twenty-five to 50 cc. is a good size for use on a pulp balance and 200 to 1000 cc. capacity should be used on a balance sensitive to 0.1 g. First fill the bottle to the top, or to a well defined mark near the top, with water and weigh. Then empty the bottle and fill half to two-thirds full of the wet sand or slime. Cover with water and shake well, removing the last traces of air bubbles by suction. Fill to the mark with water and weigh. Finally, dump out the sand or slime, dry it carefully and weigh.

$$(18)\quad \text{Density } d = \frac{\text{Wt. of dry sand}}{\text{Wt. of bottle full of water} + \text{Wt. of dry sand} - \text{Wt. of bottle with sand and water}}$$

If the sand is first dried and weighed, and a definite quantity is taken for the test, the result will be too low unless the sand is boiled in water or soaked for a long time. It is very difficult to thoroughly wet dried sand or slime. Again, wet sand must be well dried before weighing, as any contained moisture lowers the apparent density. If the wet sand contains n per cent of moisture by weight, the apparent density $= \frac{100d}{100 + n(d - 1)}$, where d is the true density of the dry material. A quick and closely approximate method for determining the density of a fine concentrate is as follows: Fill a burette to a given mark with pure water at standard temperature, weigh out carefully about 20 g. dry concentrate, and run into the burette by means of a piece of glazed paper, taking care that all goes under water. Note the increased volume due to water displaced by the

concentrate. Then the density of the concentrate is its weight in grams divided by the volume of water displaced in cubic centimeters.

It is often important to know the interstitial space in settled sand or in a filter cake. The maximum volume of voids is obtained when moderately moist material is shoveled or fed by a mechanical distributer into a vat. In a vat of sands having n per cent interstitial space, the speed of percolation will be 100/n times the leaching rate. Thus, if the solution covering a vat of sand drops at the rate of 2 in. per hour, and the interstitial space is 40 per cent, the speed of the solution descending through the sand is $100/40 \times 2 = 5$ in. per hour. Since the depth of the tank or vat is known, the time of draining or the time that a change in the strength of the solution will be apparent in the effluent solution can be closely approximated, provided the material is uniformly distributed in the vat. In settled sands, the interstitial space may range from 40 to 55 per cent.

Let w = grams of material in 100 cc. (including moisture), or lb. per cu.ft. times 1.6.
s = per cent of solids, if material is wet.
d = density of dry solid.
k = 100d/(d — 1), a constant for each material.

For dry material:

(19) Per cent voids or interstitial space $= 100 - \frac{w}{d}$

Thus, for a tailing of 2.65 specific gravity and weighing 80 lb. per cu.ft., the percentage of voids is $100 - \frac{80 \times 1.6}{2.65} = 51.7$ per cent.

For wet material:

(20) Per cent of actual voids or air space $= 100 - w\left(1 - \frac{s}{k}\right)$

(21) Per cent of total space occupied by air and water $= 100 - \frac{ws}{100d}$

(22) Per cent of volume occupied by water $= \frac{w \times \text{per cent moisture}}{100} = \frac{w[100 - s]}{100}$

Thus for partly drained tailing, weighing 95 lb. per cu.ft., with 15 per cent moisture and 85 per cent solids of specific gravity 2.5, the space occupied by air and water is found as follows:

$k = \frac{100 \times 2.5}{2.5 - 1} = 166.7$; $s = 85$ and $w = (95 \times 1.6)$

From (20), $100 - (95 \times 1.6)\left(1 - \frac{85}{166.7}\right) = 25.5$ per cent dry air space.

From (21), $100 - \frac{(95 \times 1.6) \times 85}{100 \times 2.5} = 48.3$ total interstitial space, in per cent of total volume.

The difference of 22.8 per cent is the space occupied by water.

Also from (22), $\frac{(95 \times 1.6)(100 - 85)}{100} = 22.8$ per cent of total space occupied by water.

The capacity of a filter press is most accurately determined by blowing as nearly dry as possible before opening, then selecting several pairs of frames, those of each pair being equidistant from the ends, weighing the entire contents of each frame separately and also determining the moisture in each. Average these figures to get the result per frame and then multiply by the number of frames. A quicker way is to measure the volume of effluent water from the press. This can generally be easily done, as most mills have solution meters on all important pipe lines. Also determine the water ratio, R, of the incoming pulp, and the water ratio, M, of the cake.

A test gave the following results: Water ratio of pulp 4:1; cake contained 40 per cent moisture; total effluent water = 20 tons.

Then R = 4, and $M = \frac{\text{per cent water in cake}}{\text{per cent solids in cake}} = \frac{40}{60} = 0.667$.

(23) Tons solids in press $= \frac{\text{Tons effluent water}}{R - M} = \frac{20}{4 - 0.667} = 6$ tons.

Sluices and Launders

When sluicing wet material from tanks or vats by water or a stream of solution, the calculations are complicated by the fact that water from two sources enters into the mixture.

Let C = per cent dry sand or slime in the material before sluicing
M = water ratio of material before sluicing
= per cent water divided by per cent dry solid
$= \frac{100 - C}{C} = \frac{100}{C} - 1$
R = water ratio of material after sluicing
$= \frac{100 - S}{S}$, where
S = per cent solid in the material after sluicing
E = net sluicing efficiency = tons dry solid moved by 100 tons of added sluicing solution
Q = tons sluicing solution required per ton of dry solid in material sluiced to give a product of S per cent dry solid and R water ratio.

(24) Then $E = \frac{100}{R - M} = \frac{CS}{C - S}$

(25) $Q = R - M = \frac{100}{S} - \frac{100}{C} = \frac{100(C - S)}{CS} = \frac{100}{E}$

(26) Tons water added per gross ton of wet material sluiced $= \frac{QC}{100} = \frac{C(R - M)}{100} = \frac{C}{S} - 1 = \frac{C}{E}$

Thus, if sand in a vat contains 40 per cent moisture, and it is desired to sluice it out so that the resulting pulp will have a water ratio of 3 to 1, we have

$M = \frac{40}{60} = 0.667$; $E = \frac{100}{3 - 0.667} = 42.9$; and
$Q = 3 - 0.667 = 2.33$

In the control of mill operations, it is often necessary to measure the amount of pulp flowing in certain launders. Such measurement is useful for determining the amount of feed going to some machine or the quantity of product coming from the machine.

(27) Tons dry solid per day $= \frac{\text{Pounds dry solid caught} \times 43.2}{\text{Seconds required for catching}}$

(28) Tons dry solid per day $= \left(\frac{2700d}{d - 1}\right) \times \left(\frac{p - 1}{t}\right)$

(29) Tons dry solid per day $= \frac{(27k)(p - 1)}{t}$

where t = time in seconds required to catch one cubic foot of pulp using the entire stream, p is the specific gravity of the pulp, and d is the density of the dry solid, and $k = 100d/(d - 1)$.

Methods of applying the above formulas:

Method No. 1. Turn the whole stream into a suitable bucket or tub, and, when nearly full, switch off stream, noting the exact time of catching by means of a stop watch. Dry the entire catch, weigh and apply formula (27).

Method No. 2. Turn the whole stream into a large tank, switching off after a known considerable interval, say, one minute. Measure the volume and calculate t. In a smaller vessel catch sufficient pulp so its volume can be correctly determined, approximately 1000 cc. or 1 cu.ft. Dry, weigh and calculate the dry pounds of solid per cu.ft. of pulp. Apply the formula:

$$\text{Dry tons per day} = \frac{\text{pounds per cu.ft.} \times 43.2}{t}.$$

Method No. 3. Determine the value of t as in method No. 2. Catch a moderate sized sample of pulp in a bucket and determine net weight. Then dry and weigh the pulp. Calculate S, the percentage by weight of dry solid in the pulp. Then $p = \frac{k}{k - S}$. Apply formula (29).

Method No. 4. Determine t as above. Find the specific gravity of the pulp, p, directly by means of the specific gravity flask. Apply formula (29).

Method No. 5. Single measurement for small flows: In a bucket, marked to hold just one or two cu.ft., catch the pulp, noting exact time. This gives the value of t. Find the weight of the pulp by weighing and deducting the tare of the bucket. p = weight of pulp per cu.ft. times 0.016. Apply formula (29).

Accurate Timing Essential

For accurate results, the time by stop watch for catching samples should never be less than 20 seconds, and a minute or more is to be preferred. Galvanized iron washtubs are convenient for catching small flows and wooden tanks will serve for larger flows. The importance of a sharp and clean cutting of the stream at the time of deflection and when the stream is returned to its usual channel cannot be over-emphasized. The filling of the receptacle takes place all too quickly for the most accurate results and a second's difference between the timing and the actual flow may introduce no small error into the calculations, especially when the report is made in terms of tons of solid per 24 hours. Unless a mill has been designed with launders purposely arranged to facilitate sampling, the ingenuity of the sampling crew will, in many cases, be put to the test to secure a satisfactory sample. It may be necessary to tap a launder beneath a floor or in such a cramped space that, at first, it seems useless to make the attempt. Once a sample has been taken it should be carefully handled until it is ready to be discarded. If any of the pulp is allowed to spill on the floor, the entire sample should be rejected and a new one taken. In case the whole stream cannot be deflected, the sample must be secured by making a cut across the stream as it falls freely through the air. The cutting edge of the sampler must extend through the thickness of the stream and a little beyond to insure a complete cut, and it should move at a uniform rate of speed from one side of the stream to the other. The proper speed to use is dependent upon the volume of pulp that is desired for the sample.

Once a mill has reached the point of steady and continuous operation, it is generally possible greatly to simplify calculations of performance by using certain constants in the formulas[24]. Such quantities as d, k, 27k, etc., change so little that they may safely be considered as constants. Useful curves[22] and charts[21] can be constructed, which show at a glance the relation between density of dry solid, specific gravity of pulp and tons of dry solid per day[25]. Tables showing the contents of dry solid for various sizes of tanks and per foot or inch of depth are valuable time savers.

Formulas for Heavy Solutions

Up to this point all calculations have been made upon the assumption that the specific gravity of the water or solution in the pulp has the value of unity. In some cases the presence of dissolved salts may change the specific gravity of the mill solution so that correct results would not be obtained by using the formulas given above. It is worth noting that a variation in the specific gravity of the solution has a much greater effect than a corresponding variation in the specific gravity of the dry solid. However, such cases may be considered exceptional, and the formulas already stated will usually give satisfactory results and are the ones in common use. Nevertheless, it is well to know their limitations, and formulas in which the specific gravity of the solution is considered as a variable will now be given[9].

Denoting the specific gravity of the solution as D, and using the same notation as in formulas (11) to (17)

(30) $$S = \frac{100(p - D)d}{p(d - D)}$$

(31) $$p = \frac{100D}{100 - S\frac{(d - D)}{d}}$$

(32) $$R = \frac{D(d - p)}{d(p - D)}$$

(33) Cu.ft. of pulp required to make 1 ton dry slime

$$= \frac{32\left(100 - S\frac{(d - D)}{d}\right)}{DS}$$

(34) Weight of dry slime in pounds in 1 cu.ft. of pulp

$$= \frac{62.5d(p - D)}{d - D}$$

(35) Volume of pulp in cu.ft. containing 1 ton dry slime

$$= \frac{32(d - D)}{d(p - D)}$$

(36) Percentage by weight of solution in pulp =

$$100 - S = \frac{100D(d - p)}{p(d - D)}$$

(37) Volume in cu.ft. of 1 ton of pulp =

$$\frac{100 - S\frac{d - D}{d}}{3.125D} = \frac{32}{p}$$

(38) Weight in pounds of 1 cu.ft. of pulp =

$$\frac{6250D}{100 - S\frac{(d - D)}{d}} = 62.5p$$

Variations in temperature cause a change in the volume of wet pulp. The effect of change of temperature is discussed by Clevenger, Young and Turner[10]. This article also contains extensive tables and charts dealing with the specific gravity of slime pulps.

Economic vs. Metallurgical Efficiency

In every mill there are two kinds of efficiency that require consideration. Metallurgical efficiency is concerned with the highest extraction that it is possible for individual machines and the whole plant to make. Economic efficiency is interested only in the greatest profit the plant will yield. If the two are attained at the same time, operating conditions may be said to be ideal, but this is seldom if ever the case. By crowding ore through it a mill can be made to produce a larger tonnage of concentrate than when operating under normal conditions. Though the concentrate is of lower grade, the net result is greater returns from the metals sold and generally greater profits. The metallurgical efficiency or per cent extraction may be much lower than before. Nevertheless, the increased profit more than offsets the greater loss in the tailing and the economic efficiency of the plant is increased[85]. Economic efficiency is calculated from the cost of labor, the cost of supplies and the selling price of metals. It, therefore, contains enough variables to constitute a live question to any mill management.

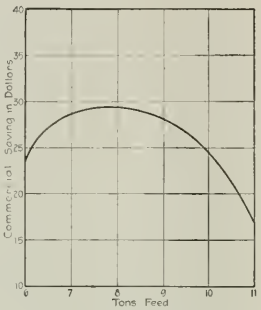

FIG. 2. ECONOMIC EFFICIENCY OF VANNER

As an illustration of the application of the principle of greatest economic efficiency the saving made by vanners treating copper ore will be considered. A chart like Fig. 2 can be made in which the value of the total metal saved per day by a vanner, less the cost of operation, is plotted against the tons of feed coming to the vanner. Such a chart shows at a glance the vanner makes the greatest saving when handling about 7.8 tons of feed per day. Of course, the relation of the product of each concentrating machine to the whole milling process must be remembered. A vanner making a fairly clean concentrate, going to market without further treatment, would not be operated in the same way if it was desired to produce a dirty concentrate which would be cleaned in a flotation machine.

Hand Sorting

The problem whether hand sorting of ore before milling will be profitable or not cannot be decided without making a close study of conditions. Sorting may have for its object the rejecting of material so low in grade that it cannot be milled at a profit, or it may be employed to keep hard and tough waste out of the mill and thereby reduce the cost of fine grinding[62]. Items such as the grade of the rejected material, the cost of sorting, milling and smelting charges and the current prices of metals all enter into the calculations that must be made. These have been expressed in formulas as follows.[21]

Let C = grade of ore before sorting
A = grade of ore after sorting
B = grade of rejected material
N = percentage of the unsorted ore that is rejected
M = milling or smelting charges, including loss in tailing
V = current price of metal exploited
P = cost of sorting per ton of sorted ore.

Then, number of tons of unsorted ore required to produce 1 ton of sorted ore $= \frac{1}{1 - 0.01N}$

Tons of waste from the above unsorted ore $= \frac{0.01N}{1 - 0.01N}$

If there was no sorting the apparent yield from the waste of grade C $= \frac{0.01NCV}{1 - 0.01N} - \frac{0.01NM}{1 - 0.01N}$

This amount is lost by rejecting the waste, and this loss must be overbalanced by the rise in value of the sorted material. This rise is (A — C) V — P. Hence the saving from sorting =

$$[(A - C)V - P] - \left(\frac{0.01CVN}{1 - 0.01N} - \frac{0.01NM}{1 - 0.01N}\right)$$

Now since the values existing in the sorted ore plus that in the waste equals that in the ore before sorting, $A + \left(\frac{1}{1 - 0.01N} - 1\right) B = \frac{C}{1 - 0.01N}$, whence

$$A(1 - 0.01N) + 0.01NB = C \text{ and}$$

$A - C = 0.01N\ (A - B)$, in which case the saving in sorting =

$$\frac{0.01(M - VB)N}{1 - 0.01N} - P.$$

This formula has been worked out on the assumption that M remains constant despite variation in tonnage, and is true for large plants. For small mills the reduction in tonnage resulting from sorting the ore would increase the cost of milling because the fixed charges constitute a relatively high percentage of the total milling cost. The value of M would then have to be changed according to conditions.

Use of Microscope

For some years the microscope has been the chief means of determining the exact nature of different kinds of ores and rocks. Thin sections, when viewed in polarized light, not only show the mineralogical composition of the ores or rocks but also the order of formation of the different crystals and their relations to each other. Many valuable geological deductions have been made from such information. Strange to say, the value of the application of the microscope to ore dressing has not, until recently, been generally recognized. Even in unskilled hands much can be learned by means of the instrument[41]. The measurement of the size of mineral grains, the size of aperture and diameter of the wire in screens, the degree to which crushing must be carried in order to free the grains of valuable minerals in an ore, the amount and condition of the middling product made by any machine and the efficiency of sulphide filming for flotation treatment are easy possibilities for the uninitiated[42]. With a little practice minerals of similar appearance can be differentiated, using the Becke

method of finding the refractive index of grains in mineral powders. The examination of polished opaque sections in reflected light may show the presence in the ore of unsuspected minerals[43]. Through the study of the shape of grains after an ore has been crushed the behavior of the ore under the usual conditions of concentration can be quite accurately predicted. A very complete mineralogical analysis of the crushed ore or concentrate produced can be made by the use of the microscope combined with a separation of the grains in heavy solutions of different specific gravities[40].

This list does not exhaust the possibilities of the microscope as applied to ore dressing. It is safe to say at any plant the cost of the apparatus and the value of the time spent in investigation will be well repaid by the increased efficiency of operation that will result from such a study. The advantages of this method of mill control cannot be too strongly urged.

Navy Department to Sell Explosives Plant

The Navy Department has begun the sale of surplus material in its possession consisting of an explosives plant at Mt. Union, Pa., lumber, chemicals, machinery, etc. Sealed proposals have been asked for on a small quantity of condemned stores and the balance will be placed on sale as fast as it is released. The disposition of the material is being made through the bureau of supplies and accounts, Navy Department, of which Rear Admiral McGowan is chief, under the direction of Lieut. C. G. Peterson.

The property which will be offered for sale by the Navy Department is small compared with the surplus material of the War Department. One of the largest items is the explosives plant at Mt. Union, which is valued at $1,500,000. Only the TNT unit will be placed on sale, the powder section having been disposed of to the Aetna Powder Co. The Navy Department announces that the purchaser will have the option of placing the plant in operation or of scrapping it.

A large quantity of copper purchased by the Department at high prices will not be sold, but will be stored for the future use of the Navy.

Storage Tanks Made of Reinforced Concrete*

Details of a Large Installation of Concrete Tanks—Preliminary Tests on Permeability for Water and Ammoniacal Liquor—Drawings, Construction, and Costs

By F. W. FRERICHS

ABOUT a year ago it became necessary to construct large storage tanks for ammoniacal liquors. Usually such tanks are made of steel, but on account of the war steel plates were not obtainable and concrete was the next best material which was available for the construction. By preliminary experiments it was proved that good concrete was not materially affected by crude ammoniacal liquor, and in order to ascertain the permeability of concrete walls by water and aqua ammonia four small experimental tanks were constructed and subjected to systematic tests.

The accompanying sketch (Fig. 1) illustrates the construction of the tanks, one of which was made from cement concrete consisting of one part cement, two

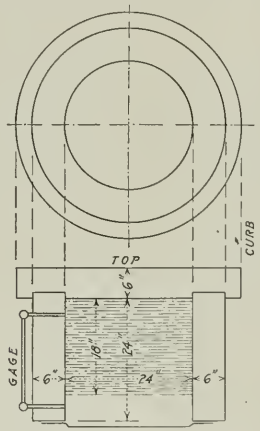

FIG. 1. SKETCH SHOWING CONSTRUCTION OF THE TANKS

parts sand, and four parts gravel. This tank was designated by the letter "A." The three other tanks were made from the same concrete mixture with the sole difference that in tank "B" 2 per cent hydrated lime was added to the cement before mixing, while tanks "C" and "D" contained 2 per cent each of two other waterproofing materials (stearates) of the market.

Each tank carried a gage glass on the side in which the level of the liquid in the tank could be observed. A sheet-iron circular cover was cemented to the top to prevent loss by evaporation. During the test period the tanks were standing in the open air exposed to the hot summer sun and the outside surfaces appeared dry. The inside area of each tank was 15.70 sq.ft.; the outside area was 35.74 sq.ft.

*Read before the Chicago meeting of the American Institute of Chemical Engineers, Jan. 17, 1919.

After ten days' drying the tanks were subjected to the following tests with a view of ascertaining the permeability of concrete by water and ammoniacal liquor:

Series I.—Permeability for Water

All four tanks were filled with water 18 in. high to within 6 in. from top, and the iron covers luted on tight with cement. Readings of water in gages were taken every day at 3 p.m. and the drop in the water level was recorded as read in inches.

Columns I—IV designate the same as in Series I.

The aqua ammonia in the tanks did not perceptibly decrease in strength in the ten days' test. The tanks were exposed to the hot sun.

Counting the decrease of the first two days for saturation of the concrete, then the average evaporation per day per sq.ft. outside area exposed to the atmosphere (25 sq.ft.) was for A 3.5 cu.in.; B 1.0 cu.in.; C 1.25 cu.in.; D 1.02 cu.in.

After these tests were made the tanks were dried out and painted on the inside with three coats of raw gas tar. The tar used for the first coat was thinned down with about 10 per cent turpentine, which caused the tar to penetrate about one-eighth of an inch into the concrete. After one week's drying the tanks were tested again with ammoniacal liquor and during several months there was no appreciable loss of their contents.

Three Storage Tanks

Encouraged by these results three large storage tanks were built by plans which were prepared by Messrs. Brenneke & Fay, civil engineers of St. Louis, who describe them as follows:

Three tanks were built in a concrete pit 47 ft. 2 in. wide, 130 ft. long and 30 ft. deep. The excavation for the pit was made in the slope of the river bank partly in earth and partly in solid rock. The bottom, side and end walls rest on solid rock. The walls of the pit are designed as vertical reinforced concrete slabs, their bottom edge being heeled into a trench cut in the rock and the top edge reinforced with a flange acting as a horizontal girder. The tops of the walls are tied across to the opposite walls at intervals by a system of longitudinal and transverse beams which are reinforced to act in either tension or compression, these beams being supported at their intersections by columns from the bottom of the pit. The walls of the pit are so reinforced as to resist hydrostatic pressure in either direction. The north and east walls, which are the upstream and river walls, are also designed to resist the impact of running ice during a high water stage.

After the side walls were built the bottom of the pit was covered with concrete to make it tight, and is reinforced with steel in both directions as a precaution against any upward pressure that might occur during high water on account of fissures or cavities in the rock underneath. In the concrete bottom, sumps are provided to collect rainwater, seepage or leakage from the tanks. Circular chases were also left in the concrete bottom in which to heel the side walls of the tanks in order to get a tight joint between the walls of the tanks and the bottom. The longitudinal and cross beams between the walls at the top of the pit are also designed to support a concrete floor should a building be constructed over the pit in the future. All concrete work in the pit is composed of one part red ring portland cement, two parts sand, and four parts washed and screened Meramec gravel. The accompanying plans (Fig. 2) show the general design, dimensions and details, as well as the steel reinforcement of both the pit and tanks.

The three tanks are 35 ft. inside diameter, and 26 ft. deep. The walls are 7 in. thick, and the tops are covered with a concrete roof 6 in. thick. Manholes are provided in the roof of each tank and are constructed with a double curb of concrete 6 in. high around the

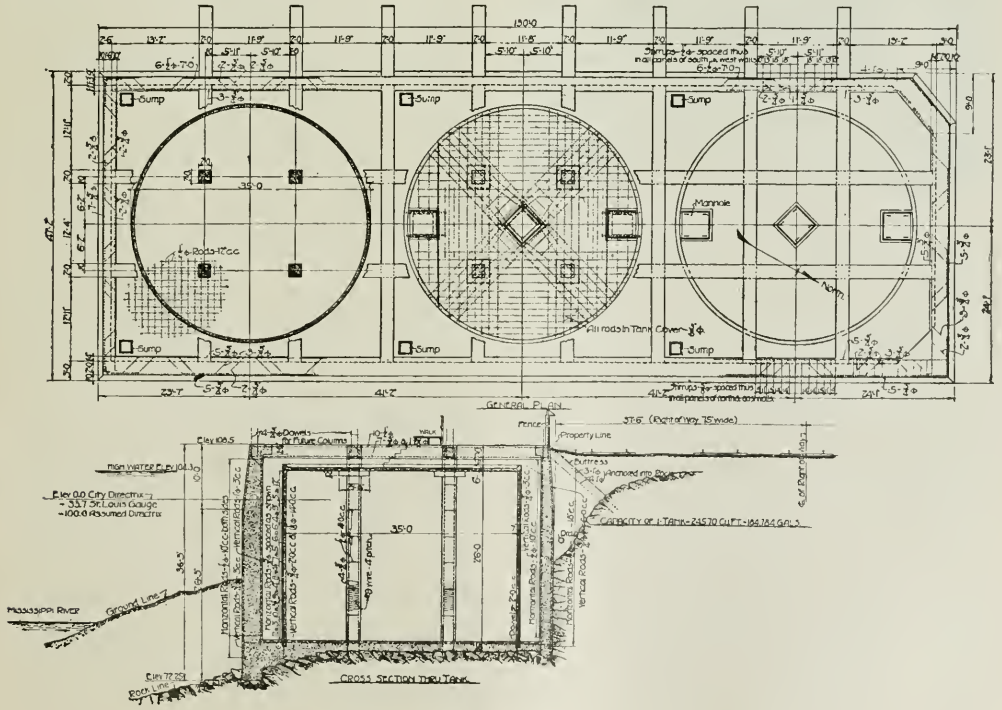

FIG. 2. PLAN SHOWING GENERAL DESIGN, DIMENSIONS AND DETAILS

openings. The manholes have metal covers in the form of an inverted pan, the edges of which rest in the groove between the curbs, and the groove is filled with water to form a seal to prevent the escape of gases from the tank.

The roofs of the tanks are also constructed with a curb about 6 in. high around the edge so that the entire roof can be covered with water as an additional seal against the escape of gases through the concrete.

Plain Concrete Tanks Watertight

As the tanks are to contain ammonia liquor it is essential that they should be tight. Preliminary to their construction several small experimental tanks about 3 ft. in diameter were built with and without waterproofing compounds mixed with the concrete. The plain concrete tanks apparently were as watertight as those in which compounds were used. From the information obtained from these experimental tanks, and from various other sources, it was concluded that waterproof tanks could be built of plain concrete. It is essential that all joints in the walls be eliminated and the concrete be mixed dry, that is, of a consistency of a stiff mortar and then thoroughly rammed. In order to eliminate all joints it was necessary to arrange to concrete continuously day and night from the time the walls were started until they were finished. The vertical reinforcing rods were first secured in position,

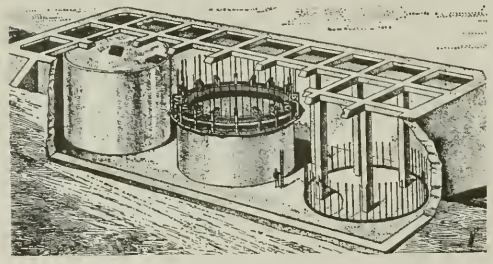

FIG. 3. PERSPECTIVE DRAWING OF THE THREE TANKS

sixteen of which were 1⅛-in. diameter plain rods located equidistant around the circle, the balance of the rods being ¾-in. diameter deformed rods.

On each of the 1⅛-in. vertical plain rods was placed a metal sleeve constructed with a pair of metal jaws so arranged as to grip the rod wherever the sleeve was placed. The outside of the sleeve was threaded full length and provided with a large nut. From these sleeves were suspended wooden yokes having a metal bearing on the nuts on the sleeves. To the yokes were attached the sliding forms for the tank wall and also the working platform for the men.

The general construction of the yokes, forms and platform is indicated on the accompanying perspective drawing (Fig. 3). The forms were about 5 ft. high made in sections bolted together. The faces were made of quarter-sawed tongued and grooved material laid vertically. After the horizontal reinforcing for the lower 5 ft. of tank was wired in place, the forms were placed and concreting started. The concrete was delivered by a chute from the mixer at the top of the pit to the working platform and deposited into the forms in thin layers and thoroughly tamped. As soon as the concrete reached the top of the forms, the movement of the forms was started by turning up the nuts on the threaded sleeves. This work was carried on continuously day and night, no stopping in the work of concreting or movement of forms being allowed from the time of starting until the wall was finished.

The placing of the longitudinal reinforcing steel was carried on at the same time. As soon as a nut reached the top of its sleeve the load on it was relieved and the nut backed down to the bottom and the sleeve slid up the rod and secured to a new position, and the process of jacking continued. The movement of the forms was made uniform by taking an equal number of turns on each nut in rotation. The rate of movement varied from about 8 in. per hour during the cool hours before sunrise to about 14 in. per hour during the heat of the day, as the time of setting of the concrete was affected by the temperature of both materials and atmosphere. After the top of the wall was reached and the concrete set, the forms were disconnected and removed and used again on the next tank. The concrete roofs were put on at a later date after the walls were thoroughly set.

The concrete in the tank walls is composed of one part red ring portland cement, two parts sand and three parts washed and screened Meramec gravel.

After the concrete work was completed and the tanks dried out the bottom, sides and roof on the interior were coated with three coats of tar applied with a brush as an additional precaution against leakage of liquid gas.

The tanks were then tested by filling with water. In the walls of the first tank built there was some leakage through slight lifting cracks which was due to the slow movement of the forms. These lifting cracks were avoided by more rapid movement of forms on the balance of the work. The leaks gradually healed up and have practically disappeared.

The capacity of each tank is about 185,000 gal., and cost approximately $10,000 exclusive of the tank pit.

Plan to Dispose of Surplus Government-Owned Nitrate

A meeting for the purpose of taking up the disposition of surplus stocks of sodium nitrate in this country was held recently in the office of the Director of Sales and was attended by a representative of the War Trade Board, a representative of the War Industries Board, the Nitrate Committee, and representatives of the Sales Office.

It developed at this meeting that the Government has a surplus of approximately 226,000 tons of sodium nitrate in the United States and 120,000 tons in Chile. It was decided that the importers should dispose of the surplus in this country and that the Government should endeavor to dispose of the surplus in Chile to foreign interests. A committee was appointed by the Nitrate Committee to draw up an offer to the Government to buy the surplus nitrate, the Government to allow them a certain fixed amount per ton to cover cost of selling.

The operation outlined is simply a continuation of the method under which the consumers have obtained sodium nitrate through the importers since November, 1917.

Economics of the Zinc Industry: A Prophetic Discussion

An Expansion of the Zinc Industry Is Not to Be Obtained by Advertising and Promoting New Uses Alone—In Addition Metallurgical Operations Must Be Perfected and Lower Costs Obtained

By PARKER C. CHOATE

WITH the close of the world war the zinc industry finds itself in a condition demanding serious consideration, with more radical reconstruction in prospect than in almost any other large industry.

Capacity for overproduction exists equal to the extent of the entire pre-war market. The present price of spelter is hardly adequate to meet expenses, even crediting the value of the acid by-product. The price of sulphuric acid will drop, since its production has been greatly stimulated by the war and the consumption has suddenly been heavily curtailed. The labor charges are exorbitant and at best are a large factor in the existing methods of spelter manufacture. The fuel (coal) has increased abnormally in price due to increased labor and freight. Freight tariffs have increased so much that the industrial economic balance is seriously affected, since the zinc smelter must not only meet long freight hauls on ore but a distant distribution of acid and spelter.

Cost to Remain High

Thus the cost of making spelter, of raw material (ore, clay, coal), of labor and freight will probably remain high for a long period, while the selling prices of zinc and acid appear to be on the decline owing to overproduction. To comply with nature's law of demand and supply the best course seems to be to increase spelter consumption and at the same time to decrease the cost of production, since a decreased selling price is the surest means of increasing sales. The American Zinc Institute has already been formed for the purpose of regulating and finding new markets for the metal at home and abroad. This united effort is the first instance of co-operation within the zinc industry, and is very creditable, but so far it has appeared to overlook the real essence of its purpose—largely increased sales—because it is not proposing any radical steps to decrease present manufacturing costs. To increase a market by finding new uses for a commodity by advertising is a favorite method, but it tends to increase the cost of production by the added costs of the advertising propaganda, while the increase of a market by a decreased offering price of the product is automatic. It would therefore seem desirable to discuss the problem of how to produce spelter more cheaply, as the problem of increased sales can safely be left to the advertising agencies now available. However, both methods are very desirable in this instance, since zinc can undoubtedly be advantageously adapted to many new uses.

The best economic weapon with which to meet a bad business situation is not employed or discussed because to decrease the cost of production involves technology and mental development seldom present on the board of directors.

Centers of Present Spelter Production

The sheet-zinc fields lie in the Middle West and have furnished the main ore supply in the past because of the quality of the ore. These fields still play a major but declining rôle because the vein deposits, chiefly of the Northwest, yield the zinc unit at a cheaper mining cost when it is shared by other metals contained in the ore. Fortunately for the older practice, the metallurgy involved in handling the large deposits of cheap vein zinc has been more difficult and so far neglected by the non-technical minds in control of the spelter trade.

When the zinc industry started in America it was natural to locate the manufacturing plant near a bed of coal, because it required several tons of coal for each ton of zinc ore reduced. Clay beds also played a part in the location, as the zinc retort was a prominent item of operating expense. Thus the industry became centered in the Middle West on coal beds and utilized the best-quality zinc ore from the nearest sheet ground. Gradually the fuel consumption has been reduced and is now about one ton of coal for one of ore; a poorer and cheaper quality of zinc ore is also handled and sulphuric acid manufacture installed in order to mitigate the SO_2-gas nuisance caused by the necessary desulphurization.

Future Importance of Vein Ores

The profits on acid and metal-carrying residues have decreased the cost of producing spelter and therefore complicate the economics, but it is unquestionable that the conditions as just outlined and which have created the old zinc industry are now passing.

It is common knowledge that the Northwest and in fact all the Rocky Mountain region contain immense quantities of vein zinc ores of complex character but which are not now carried to market to any extent. The contained zinc has been a curse to the blast-furnace operator smelting for other metals, who consequently penalized the shipper. However, concentration followed by selective flotation is rapidly changing this situation, so that increasingly large quantities of zinc mineral separated from complex vein ores are now being sold to zinc smelters.

The freight tariffs on the long haul from Western mines to the distilling plants in the Central states has been a serious and increasing item of expense, and the inevitable issue will be that the zinc concentrates will be reduced to spelter at or near the point of origin. Ample coal and proper clays do not exist there, nor can sulphuric acid be produced on account of the dis-

tance to market. Fortunately, however, water power does exist as a commodity now undeveloped and valueless; but developed it can compete with coal as a heating agent. Research is also perfecting metallurgical processes to use this hydro-electric power to reduce the heavy labor bill during distillation, to avoid the excessive use of clay and coal and to save more directly a larger proportion of by-product metals.

Leach-electrolysis of complex zinc ores is already established and controls the pure zinc market, but is not a serious competitor of ordinary metal. Electric zinc smelting is probably coming, but presents difficulties in the condensation of the metallic vapor. Electric retorting will probably be the most serious competitor of the present gas retorting, as it eliminates coal, clay and excessive labor bills, and can be installed in small units at any mine having water power. This process will use the lime-briquet reduction process, thus avoiding roasting and acid problems, and by saving the associated lead and silver in the act of distillation without the cost of residue smelting will produce spelter at a materially lower cost than is at present possible in the gas-fired or coal-fired retort.

The coming cheap electrical manufacture of spelter at the prolific vein mines using the new processes of technology presents the strongest and most immediate incentive for the distiller to reduce his now excessive cost of manufacture and to improve the metal extractions. It will produce a market for the miner operating a complex zinc ore property not now profitable; and their number is legion. The gas-retort operator must meet this competitor or disappear.

Improved Gas Retorting

I have already discussed the principles which appear to underlie any radical reduction of the cost of retort spelter in Chemical & Metallurgical Engineering, July 1, 1918 (Vol. 19, p. 20), under the title "Research Preparedness in the Zinc Industry." Briefly, the scheme involves costless fuel, lime-briquetting and continuous retorts—admittedly radical changes scrapping the present zinc plants except the organization, general metallurgical utilities and buildings.

Located on the lignite and bituminous fields of the Middle West, the zinc industry has at hand an immense latent gas supply. To make other than a low-grade producer gas will yield a carbonaceous residue, and as the coals are not free coking, the sale of the pulverized residue as such is out of the question. Hard briquetted with its own tars, however, it is a better domestic fuel than coke, and the public will pay a price for such briquets that will pay all mining and treatment costs. Thus an excess retort gas of good calorific power can be obtained as a by-product at no cost to be used in zinc distillation, while the original carbon residue is the best zinc-retort carbon mix obtainable.

Due to the character of the flotation slimes that constitute an increasing proportion of the distiller's ore-supply the act of desulphurization is rendered continually more difficult. Returns from sulphuric acid bolster up the roasting department, but its profitable manufacture is becoming questionable, even though it is a hygienic necessity. The logical solution is the adoption of the lime-reduction process, retorting the briquets of raw ore, a process which has demonstrated its ability to decrease largely the wear and tear on retorts, to increase materially the metal extraction, to conserve about 33 per cent in time of distillation with a corresponding saving in fuel and labor and to be about the only good way to handle the fine flotation slimes.

The continuous vertical zinc retort, with center condenser of large diameter, preheating the charge in the top section, conserving waste heat by preheating the combustion air and gas in the bottom or discharge section, will in the first place greatly reduce the labor bills, but will also conserve heat units beyond the best systems now in use. A form of vertical retort is reported in use in Germany, but America will produce an advanced and durable type using the non-slagging lime briquet.

The technical mind realizes that these economies in gas-fired distillation are practical and must be embraced if the present industry is to be protected. They will cheapen the cost of manufacture and enable the use of the cheapest zinc-unit irrespective of quality.

Economic Summary

Gas-retort practice can conserve one-half or more of its labor bills by adopting the large continuous vertical retort. Fuel gas and retort mix can be obtained at no cost (perhaps at a minus cost, or profit) by entering the lignite retorting business and supplying a large consuming public with suitable domestic coal briquets.

Further conservation in fuel gas, carbon mix and retort wear and tear is obtainable by using the lime-reduction process, at the same time using cheaper complex ores and giving better metal extractions.

In this manner, it is probably practicable to distill a ton of zinc ore with less than one-third ton of coal or its equivalent gas. While it is undesirable to enter into definite figures as to the cents per pound saved by this or that departure from the existing crude practice, it seems obvious that more than 50 per cent of the present cost of spelter can be conserved while utilizing a cheaper zinc unit than the usual concentrate from the Missouri-Kansas-Oklahoma fields.

The present zinc industry must take such steps or practically be driven out of business by more advanced operation. An increased market for spelter cannot be of aid if the present manufacturing cost is to remain.

United Economic Research

While the American Zinc Institute is preparing a market by united effort, it is advisable to unite in large scale research with a view of enabling the present industry to maintain itself, to serve the public with better technical efficiency and to aid in the larger distribution of zinc, by offering the metal at a lower price.

The usual research of individual corporations is quite inadequate in finance or scope to meet such an issue as now presents itself, and the cost of erecting and operating a commercial unit is larger than most zinc companies care to assume. No doubt inventions will be involved and compensation should be paid to the designer or creator. Under united experimental action the entire cost of the tests can be assumed by the agents who perfect the technical advance, the so-called cost of research thus becoming a prepayment on account of the royalties that would later accrue.

While it may require a quarter of a million dollars to practically develop the obvious advances, such a cost will be small as compared to the total which will be incurred by the individual efforts of each corporation experimenting with this and that process or device, or of paying large royalties to some exploiting corporation, which, like Minerals Separation, obtains control of essential patents.

The outlined research is known to be practical, and all that is needed is a balanced assembly to produce the desired result, so that the operating and engineering staff of the contributing zinc corporations can copy and adapt it to suit their several needs. The writer two years ago pointed out that these improvements in the zinc industry consisted of a chain of acts, radical, but connected. To test or adapt one of the proposals will lead to another, so that only a complete installation will yield the desired result.

The subject is submitted for thought and discussion.

Essex, Mass.

Corrosion of Brass in Sea Water

By Paul T. Bruhl

THE corrosion of brass has long been investigated, notably by a committee appointed by the Institute of Metals (London), and experiments have been conducted not only to throw light on the various factors governing the rate of corrosion but also to suggest some other alloy as a substitute for brass if sufficiently effective protective measures cannot be found.

Brass may be said to corrode in two ways; in the first the action is merely mechanical and the metal is abraded; in the second and more dangerous way it is either attacked uniformly over its entire surface or corrosion is strongly localized and we have the phenomena of dezincification and pitting. As the strength of a chain is that of its weakest link, so that of a condenser tube depends upon the length of time which suffices for the development of the first perforation.

In the investigation of the effect of strain it was found that the method of manufacture does not permit of any difference in solution pressure greater than 0.0002 volt. This factor contributing to the rate of corrosion is therefore not a serious one; the anodic areas merely act as loci at which corrosion tends to start and from which it spreads over the whole surface.

The bearing on the subject of annealing—with respect both to time and temperature—has been shown to be small, though annealing by increasing the electromotive force increases the liability to attack. It must always be remembered, however, that corrosion is a complex problem and the reactions it involves are difficult to foretell; so that observations made at the beginning may not hold good at the end of an experiment.

Rolling of the metal has an influence inasmuch as it increases the tendency to corrode by imparting to the metal an added energy, though the solution pressure is diminished by the closer agglomeration of the molecules.

Bilge water and organic oils are harmful, the former owing to the formation of corrosive sulphur compounds, the latter because of the decomposition by steam into products containing free acid.

Stray currents of electricity undoubtedly exert a pernicious effect by causing more rapid removal from the solution of the charged ions. Mr. Milton in discussing this point said, "If, for instance, there is a leakage from the positive cable in such a position that part of it proceeds to the sea (earths) through the water flowing through the condenser tubes, which are, of course, clean metal, instead of through the hull of the vessel, which is kept painted in order to prevent any actual contact between the iron and the sea water, some electrolytic action must take place in the tubes themselves."

I studied the influence of various corrosion products on the rate of corrosion by arranging them in the electrochemical scale and by determining their specific resistances.

The following results, which are approximate, were obtained:

1. Brass.
2. Zinc oxide.
3. The oxychloride.
4. Iron oxide.
5. Cuprous oxide.
6. Cupric oxide.
7. Iron hydrate.
8. Basic zinc carbonate.
9. Coke.
10. Basic copper carbonate.
11. Tin oxide.

The next table gives the order of resistance per cubic centimeter in ohms in the moist state.

1. Coke, less than 1000.
2. Cuprous oxide, less than 1500.
3. Iron oxide, less than 2800.
4. Basic zinc carbonate, less than 4000.
5. Basic copper carbonate, less than 6500.
6. Zinc oxide, less than 7000.
7. The oxychloride, less than 7500.
8. Cupric oxide, less than 10,000.

We see from the tables that the rate of corrosion must be to some extent increased by the mutual interaction between the products of corrosion and by the formation of voltaic couples with the metal itself.

The main consideration in any research on the corrosion problem ought to be the determination of the circumstances which give rise to pitting. Three factors govern the positions of the serious pits; mechanical defects, the presence of certain deposits which act as cathodic centers, and dezincification, that is to say, the preferential solution of the zinc. A spill must be a source of danger (though some do not hold it to be so) as the metal wall where it occurs is thinner and hence corrosion has not so far to proceed to cause a perforation. The deposits which are generally conceded to be injurious are the green oxychloride (which promotes dezincification), carbon and ferric hydrate.

A study of the effect of physical constitution on corrosion has been made. For instance, Muntz metal, which contains 60 per cent copper and 40 per cent zinc, is built up of the alpha and beta phases and the voltaic action between the two accelerates the rate of corrosion, so that at first, before secondary reactions set in, Muntz metal corrodes faster than 70/30 brass which consists of the alpha phase only.

Control of the condenser temperature through the provision of an adequate area of condensing surface, the use of electrochemical protection, the substitution for brass of other metals such as phosphor-bronze, monel metal, alloys of copper and aluminium, and brass with 2 per cent lead, have all been suggested as aids to the partial prevention of corrosion.

Other interesting observations that have been made are that up to a certain point dilution or aëration of the sea water, and in general a rise in temperature or an increase in the amount of CO_2 present, promote the corrosion of brass.

Laboratory Electro-Deposition Plant

By Carle R. Hayward

ONE of the required operations in the metallurgical laboratory of the Massachusetts Institute of Technology is a study of the electrolytic refining of copper. For this purpose a series of five tar-lined vats were used for many years, but part of the value of the operation was lost because the students could not see what was taking place in the vats.

When equipping the new laboratory in Cambridge the writer designed a set of tanks with glass sides which

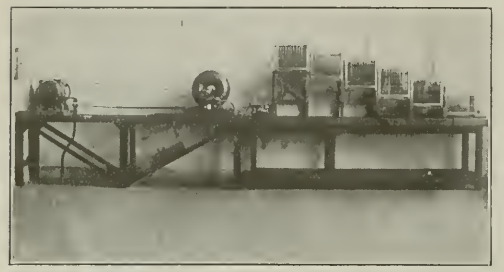

FIG. 1. LABORATORY APPARATUS FOR THE ELECTROLYTIC REFINING OF COPPER

have given excellent satisfaction. A description of the plant will doubtless prove of general interest.

A photograph of the apparatus is shown in Fig. 1 and gives a good idea of its arrangement. A 2-hp. motor is seen at the extreme left belted to a small dynamo which furnishes low voltage current for the process. There are five vats arranged in cascade. Each vat contains four anodes and five cathodes arranged in multiple. The vats are fifteen inches long, seven inches wide and twelve inches deep on the inside. The surface of each electrode submerged in the electrolyte is six inches square.

A vertical section of one of the vats is shown in Fig. 2 and a composite plan and horizontal section is shown in Fig. 3. Both these sketches are to some extent self-explanatory.

It will be noted in Figs. 2 and 3 that the ends of the vats are of slate grooved to receive the slate bottom and the glass sides. The parts are cemented together with litharge and glycerine and held firmly in place by steel tie rods, of which there are two on each side. Each vat has a lead overflow spout on one end and a lead spout in one corner of the bottom for cleaning out the anode mud. The bottom spout is kept closed by a rubber stopper.

Copper rods $\frac{1}{4}$ inch in diameter serve as bus bars. These are held on the upper edges of the glass sides by means of a spring clamp at each end. Shallow cross grooves are filed in each bar $1\frac{1}{2}$ inches apart to keep the electrodes properly spaced.

The electrodes are riveted to strips of sheet copper, which are passed over and soldered to $\frac{5}{16}$-inch copper supporting rods. This is shown in the electrode drawing Fig. 4. A piece of rubber tubing is slipped over one end of each support bar to insulate it from one of the bus bars. By this method the bus bar on one side of the vat will have contact with all the anodes and be insulated from the cathodes while the reverse condition will prevail on the opposite side of the vat.

The cathode bus bar of one vat connects with the anode bus bar of the next vat, etc.

The electrolyte overflows through a lead spout from the upper vat into a lead pipe, which conducts it to near the bottom of the next vat. In a similar way it passes through the five depositing vats to a sixth vat, from which it is siphoned to the well of a Pohle air lift delivering to the upper vat. The rate of circulation can be varied at will by adjusting the air lift.

In the class work it is customary to operate the plant at ten to fifteen amperes per square foot of cathode surface and two-tenths to four-tenths volt between electrodes. No attempt has been made to heat the electrolyte, but this could probably be done if desired. The vats have been used only for depositing copper, but there is no apparent reason why they could not be utilized for work on other metals.

The only difficulty encountered thus far has been the tendency of the acid to eat the slate at the surface of the electrolyte. This has been prevented by coating with acidproof paint.

In operating the plant the students make all necessary electrical observations, weigh the cathodes before and after the test, sample the electrolyte before and after the test, note the rise in temperature of the electrolyte, etc. At the close of the test the electrolyte is siphoned into glass carboys and the anode mud cleaned out, dried and weighed. After the necessary analyses an account of stock of copper, arsenic and precious metals is made, the electrical efficiency calculated and a neostyle sheet prepared giving in tabulated form all data and calculations.

Fuel Economy in the Boiler House—II

A Description of the Types of CO_2 Recorders Used in America and Europe and Principles Involved in Their Operation—Sarco, Uehling, Simmance & Abady, Cambridge Bi-Meter, Auto and Mono-Recording Instruments

By JOHN B. C. KERSHAW

In the previous article[1] the writer showed how important was regular and systematic testing of the waste gases from boiler plants, in connection with the urgent need for economy in the use of fuel, and also pointed out that automatic gas-testing apparatus could be of great service in assisting the boiler engineer to obtain the highest possible efficiency from his plant. The best method of connecting the testing apparatus to the boilers and flues was then described, and the need for placing the apparatus in charge of a properly trained man was emphasized. Corroboration of the remarks which the writer made on this subject of skilled supervision is found in an article which was published in an English technical journal before the war by a power station engineer, under the title of "CO_2 Recorders in Power Stations." This correspondent pointed out that many of the failures of automatic gas-testing apparatus in the past had been due chiefly to the defects in the installation and management of these machines, rather than the fundamental defects in their design. The advantages of the recording type of apparatus were stated to be:

"(1) That it shows at any and all times the percentage of CO_2 being obtained, so giving a guide to engineers in charge and firemen as to the conditions prevailing in the furnaces; (2) it is an index to the correct thickness of fire under different conditions; (3) it is a guide as to the correct amount of draught to be given to the fires under varying conditions; (4) it is an index of any air leakage at all points between the furnaces and the position in the flues where the gas for analysis is taken from."

The writer is aware that the U. S. Bureau of Mines has published two valuable bulletins, Nos. 91 and 97, dealing with "Sampling of Flue Gases" and "Automatic CO_2 Recorders." He has made some use of the latter bulletin in compiling the descriptions given below, but only five recording types of instruments were tested by Messrs. Barkley and Flagg in their investigations, and are described in Bulletin 91, whereas double this number are on the market and have been used in Europe and America. Since no independent description of the various types of CO_2 recorder has yet been published in this journal, the writer has thought it well to collect in one article the available information on the subject, and below all the leading types of automatic gas testing and recording apparatus are illustrated and described, with notes upon their respective advantages and defects.

The "Ados" or Sarco recorder is the oldest and most widely used form of testing apparatus for obtaining continuous and regular records of the CO_2 contents of the waste gases. Fig. 1 shows the latest form of the Sarco recorder. The power for actuating the instrument is supplied by a fine stream of water with a head of about two feet which enters the tube shown on the right hand side of the figure. The rate of flow, and therefore of operation, can be varied by altering the size of the jet used for the small glass injector. The water admitted gradually fills the measuring vessel shown in the center of the figure, and when it reaches a fixed point on the tube connecting this vessel to the gas supply, the water is automatically siphoned out, and 100 cc. of the gas to be tested are drawn into the vessel. This gas, as the water again rises in the measuring vessel, is forced into the solution of caustic potash (sp. gr. 1.27) contained in the large vessel shown on the left hand bottom corner of the figure, and as the gas bubbles up through this solution, any carbon dioxide contained in it is absorbed. The residual gas now passes up into two tubes containing floats, placed directly above the absorption vessel, and by suitable

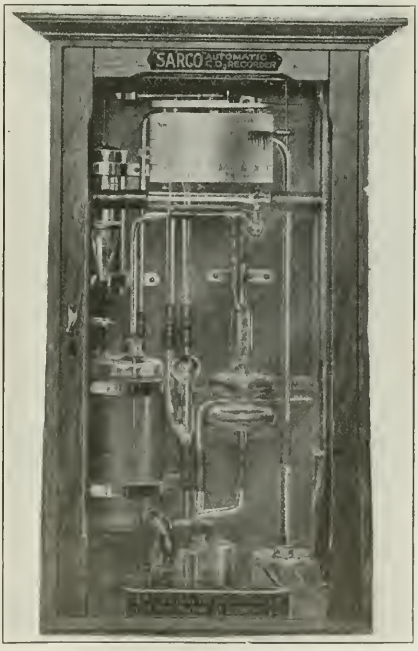

FIG. 1. THE SARCO CO_2 RECORDER

[1] CHEMICAL & METALLURGICAL ENGINEERING, Vol. 20, No. 4, Feb. 15, 1918.

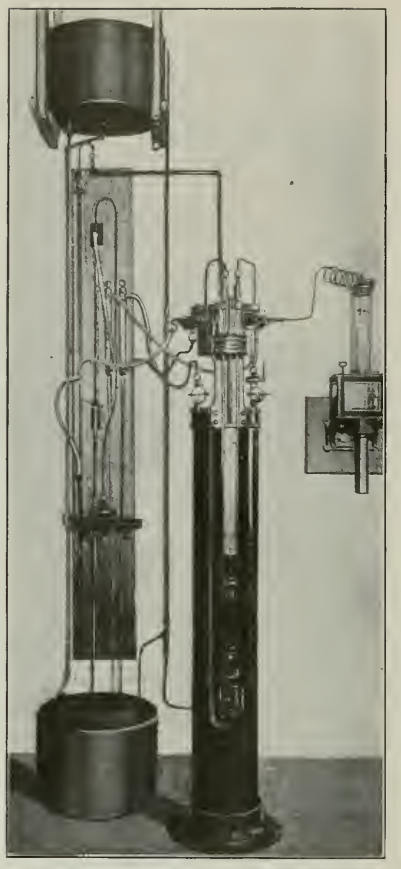

FIG. 2. THE UEHLING GAS COMPOSIMETER

mechanism records are obtained, on the paper attached to the revolving drum, of the volume of the residual gas.

It is customary to arrange the controlling mechanism so that samples are drawn from the flue at intervals of ten minutes, and the KOH solution requires renewal according to the frequency of the tests made.

The Uehling Continuous Gas Composimeter

The Uehling gas-testing instrument is based upon the law which governs the flow of gas through small apertures. The gas-containing vessels of different capacities are placed in connection with a steam-jet aspirator and with the flue. The apertures connecting the smaller vessel with the other, and the second or larger vessel with the flue, are small and of equal size. When the aspirator is set to work, a partial vacuum is produced in both vessels, consequent upon the fact that gas is being drawn out of them more quickly than it can enter, and the vacuum as measured by manometers attached to each vessel is found to be twice as great in the smaller as in the larger vessel. If now the gas passing through the larger vessel be submitted to the action of a solvent which absorbs and withdraws one of its constituents, the vacuum in the second chamber or vessel will be increased and the difference between the partial vacuum in the two vessels will be diminished in like ratio. The absorption of CO_2 from furnace gases by caustic potash can therefore be utilized to cause differences in the pressure ratio in the two gas vessels, and by proper calibration a means for ascertaining the percentage of CO_2 in the gases is obtained.

To embody this principle in a practical apparatus the following conditions must be fulfilled: (1) The gas must be brought into the apparatus under a constant tension, and must be drawn through the two apertures with a continuous and uniform suction. (2) Both apertures must be located in a part of the apparatus which is maintained at a constant temperature. (3) Provision must be made for keeping these apertures perfectly clean. (4) The larger chamber must be made perfectly gas-tight. (5) The constituent to be absorbed (CO_2) must be entirely removed while the gas is passing through this part of the apparatus.

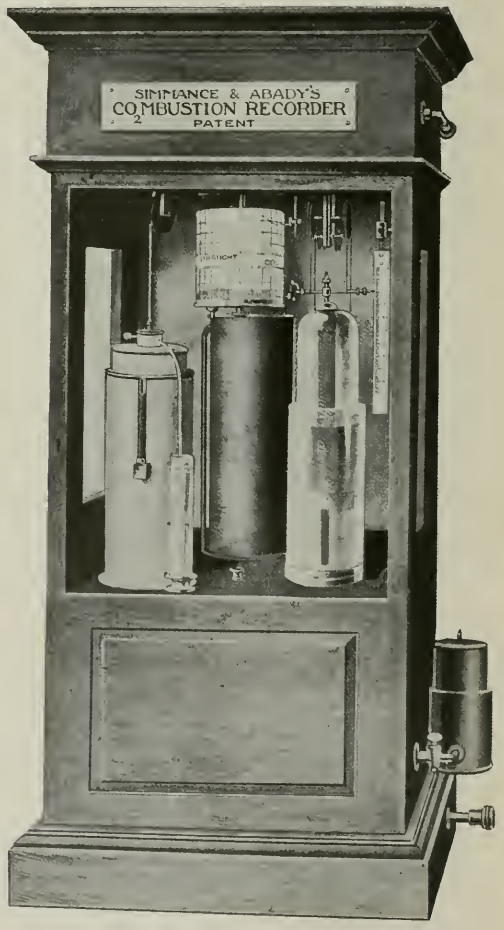

FIG. 3. THE SIMMANCE & ABADY CO_2 RECORDER

The Uehling instrument is made in two forms, the first with, and the second without, a recording pen and drum. Fig. 2 illustrates the latter type.

The Simmance-Abady Recorder

The Simmance-Abady recorder is illustrated in Fig. 3, and in some of its features resembles the "Sarco" apparatus, for water supplies the motive power and the CO_2 is absorbed by bubbling through a solution of caus-

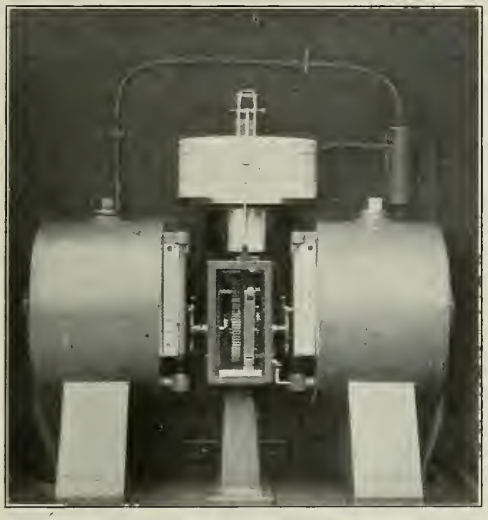

FIG. 4. THE CAMBRIDGE BI-METER CO_2 RECORDER

tic potash, contained in a steel vessel enclosed in the lower portion of the case which contains the apparatus. About 600 cc. of the flue gases are drawn from the flue at definite intervals of time, and a measured portion of this volume is employed for each test in that portion of the apparatus called the "analyzer." When the flue gas has been transferred from the "extractor" into the "analyzer," the CO_2 is absorbed, and owing to such absorption the analyzer bell will not rise to its full height. It is allowed to work automatically and to rise as far as it will, where it remains for a few seconds and then drops a little, as the heat of the chemical combination disperses and the absorption is completed. At this point a pen descends, and marks downward from the zero on the chart to the position of the analyzer bell.

A boxwood scale on the side of the recorder tank is graduated to show 100 per cent CO_2 at the bottom and 0 per cent at the top. The capacity of the bell shown on the left in the figure is such that when the test is made with air the whole of the sample is transferred to the recorder bell on the right, which then rises to the zero point on the scale. When a sample of flue gas is admitted into the appa- extractor bell through the analyzer vessel into the recording bell, but owing to the absorption of CO_2, this bell does not rise up to its full height, and the deficiency is registered by the fall of the pen to the point reached by the top of the tank. The bell then discharges its residual gas, and sinks to its original position in readiness for a new charge of gas, minus its CO_2 contents.

The Bi-meter CO_2 Recorder

The principle upon which the Bi-meter CO_2 recorder is based is that of measuring the flue gas, before and after the absorption of CO_2, by two ordinary gas meters, the actual absorption occurring in a vessel containing caustic lime, and the temperature of the gas before and after absorption being controlled by water cooling, in order to eliminate errors due to the difference in volume caused by temperature changes. Fig. 4 shows the appearance of the instrument. The gas is drawn through the apparatus by means of an aspirator, and the difference between the speeds of the two gas meters provides a measure of the amount of CO_2 in the gas. These meters are connected by a differential gearing to the mechanism that actuates the recording pen. After a certain definite volume of gas has passed through the first meter, the pen is made to drop to its initial position, from which it starts to rise again at a speed dependent on the proportion of CO_2 absorbed. The maximum number of tests per hour possible with this type of recorder is 25, and the number can be lowered by reducing the volume of gas passing through the meters. The record chart for 24 hours is 15 inches long, and the drum carrying it is seen in the center of the figure.

The Auto-Recorder

The auto-recorder is shown in diagrammatic form in Fig. 5 and, like the two first described, the instrument depends upon a stream of water for its motive power

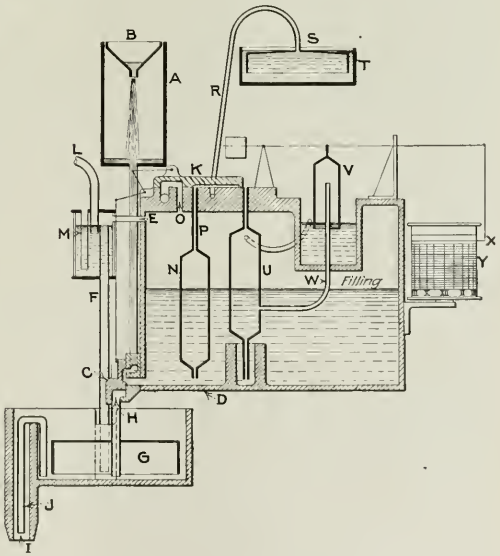

FIG. 5. THE AUTO-RECORDER

and upon caustic potash as the absorption chemical. The water enters the apparatus by the funnel *B*, and passes down into the large vessel *D* through the sliding valve at *C*. When the chamber *D* is quite filled with water.

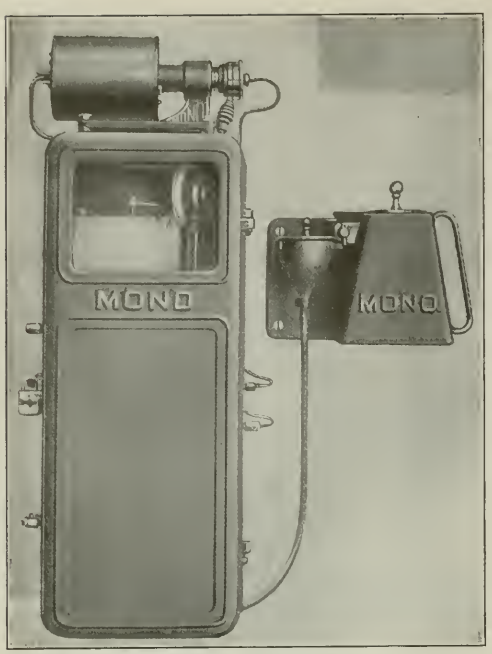

FIG. 6. THE MONO AUTOMATIC CO_2 AND CO RECORDER

this overflows by the pipe *E* into the vessel *M* and thence into the lower vessel containing the float *G*, and the consequent rising of this float causes two motions which start and carry forward the testing operation. In the first place, the float as it rises pushes up the valve *C* and closes the water supply at this point, at the same time opening the passage *H*, by which the water escapes from *D* and draws in a sample of the flue gas through *E* and *I*. In the second place, the rising of the float *G* causes the sliding valve at *K* to move to the right, and puts the measuring vessel *N* into communication with the tank *D*, through the passage *O*, so that a sample of the gas passing into *D* is also drawn into *N* as the water sinks. When the tank *D* is quite emptied, the siphon at *J* comes into operation, and, by discharging the water from the lower tank, causes the float *G* to fall and the valves *C* and *K* to return to their first positions. *D* and *N* therefore are now slowly filled again with water, and the surplus gas in the former is forced out into the atmosphere, while the measured volume in *N* is forced up through the pipe *R* into the absorbing tank *T*, where it collects under the bell *S*, and is speedily deprived of its CO_2 by the caustic potash solution contained in this tank. When the tank *D* again overflows and the discharge of the water again causes the movement of the sliding valve at *K*, the residual gas under *S* is drawn through *R* into the second measuring vessel *U*, and any deficiency of gas required to fill *U* (due to the absorption of CO_2) is made up by withdrawal from that contained in the bell *V*, suspended from a weighted lever to which is attached the recording pen at *X*. The downward movement of this lever after each test is completed therefore gives a measure of the percentage of CO_2 in each sample of gas drawn into *N*, and is recorded on the clockwork drum chart shown at *Y*.

The Mono Recorder

The Mono recorder differs from those previously described in the fact that it is a combination CO_2 and O recorder and may be used for either gas, while by the addition of a further appurtenance it is possible to make the instrument record the percentage of carbon monoxide. The power which actuates the mechanism of the instrument is derived either from compressed air or water, mercury being employed in the measuring portions of the apparatus, where the gases come into contact with the fluid medium. The gas, after being cooled and measured, is deprived of its CO_2 by bubbling through a caustic potash solution contained in the tank, shown in Fig. 6. The residual gas then passes up into the measuring bell, which actuates the recording mechanism, precisely as in the Sarco and Simmance-Abady instruments.

When it is desired to record oxygen, the gas stream is made to pass through an electric oven fixed on the top of the instrument, in which the oxygen is brought into contact with heater carbon, with formation of CO_2 in equivalent amount. The gas issuing from the oven is then cooled and passed through the remainder of the apparatus as before, the difference of the two

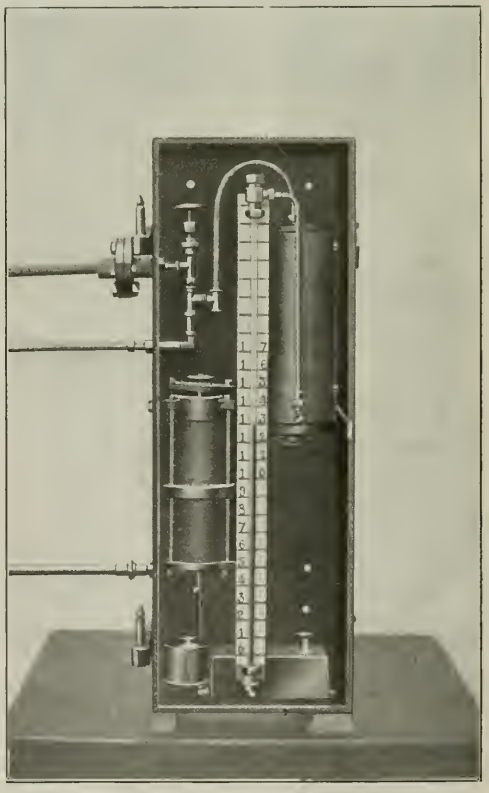

FIG. 7. THE WEBSTER W. R. COMBUSTION INDICATOR

consecutive tests giving the percentage of oxygen contained in the gas. Carbon monoxide is determined in the same manner. This method of estimating the oxygen and carbon monoxide, however, is dependent upon there being no other gases present which will combine with carbon at a red heat, and a mixture containing hydrocarbon gases, carbon monoxide, carbon dioxide and oxygen cannot therefore be analyzed in this manner.

The Webster W. R. Combustion Indicator

As its name implies, the Webster W. R. combustion indicator is not a recording apparatus, but gives a continuous reading of the CO_2 present in the boiler or chimney gases. Fig. 7 is a diagram illustrating the principle upon which this CO_2 indicator works. A water or steam aspirator (on the left) draws the flue gas continuously through the instrument, and after passing through the filter the gas enters a chamber containing a porous pot charged with a solid absorbing medium, for CO_2 gas. This chamber and pot are connected, as shown, by two vertical pipes, or tubes, with a vessel containing water, and the difference in pressure between the gas in the outer chamber and that inside the pot, due to the absorption of CO_2, causes the water to rise in the pipe that connects the porous pot with the water tank. By aid of a graduated scale attached to the latter pipe, the percentage of CO_2 can be read off directly, $\frac{3}{8}$ of an inch in height being taken as equal to 1 per cent CO_2. The "indicator" is said to respond quickly to any changes in the composition of the flue gases, and if placed in a position where the fireman can see the fluctuations of the water column, it provides him with a useful help to the efficient control of his fires. The cartridge containing the solid absorbent is said to require renewal only every other day, but the period for which it will act efficiently depends, of course, upon the CO_2 contents of the waste gases.

Eliminating Phosphorus and Sulphur in Electric Ferromanganese Furnaces

By Jay Lonergan

IN HIS discussion of the paper of Robert M. Keeney, presented at the Colorado Meeting of the American Institute of Mining Engineers, H. W. Gillett mentions the fact that recent experiments have indicated that it may be possible to eliminate a large proportion of the phosphorus from high-phosphorus manganese ores. It is thought that it would be interesting to the producers of ferromanganese to have published the methods which have been tested, and in this respect the following notes may be of value.

When the first furnace of the Iron Mountain Alloy Co. was started an attempt was made to smelt a high-phosphorus ore by carrying an excess of lime. This run lasted several days and was a failure. The ore contained about 0.32 per cent phosphorus, and the resulting ferromanganese about 0.6 per cent phosphorus. After this trial, all high-phosphorus ore was mixed with sufficient low-phosphorus ore to give a charge with a phosphorus content of about 0.15 per cent. With a mix of this nature no trouble was experienced in keeping the phosphorus content of the ferromanganese under 0.25 per cent, the maximum limit set by consumers.

A test has just been completed, however, which had the object of determining the proportion of both phosphorus and sulphur which can be eliminated by ordinary practice. This test will partially answer Mr. Gillett and others interested in such questions. The results are given in Tables I and II. Table I gives the analysis and make-up of the charge used, while Table II gives the resulting products from this run. Column 7, Table II, shows that 52.6 per cent of the phosphorus is retained by the metal, while the unaccounted losses (obtained by difference) show that 31.4 per cent is carried off through the ventilators.

While no tests have been made to determine the proportion of mechanical and volatilization losses, from observation I should say that the greater part is a purely mechanical loss, therefore the phosphorus in the dust is still retained in its original form. In case the phosphorus were volatilized it would probably indicate its presence by PH_3 gas, poisoning some of the furnace men. To date there have been no cases of poisoning.

Using the results of the above test and determining the maximum allowable percentage of phosphorus in a manganese ore to produce a metal containing a maximum of 0.25 per cent phosphorus, it took 2830 lb. dry ore to make 1000 lb. ferromanganese. On the basis that 52.6 per cent of the total phosphorus charged will go with the metal, no more than $4\frac{3}{4}$ lb. phosphorus can be carried in 2830 lb. ore and about 1760 lb. coal and lime.

Assuming that the latter contains 0.34 lb. phosphorus, the ore can contain 0.17 per cent. This figure is substantiated by the results of several months' run of the furnace previously mentioned.

Column 4, Table II, shows that at least 98 per cent of the sulphur in the charge is eliminated.

Iron Mountain Alloy Co.,
Denver, Colo.

TABLE I. FURNACE CHARGE

	1 Weight in Lb.	2 Per Cent. S.	3 Lb. S.	4 Per Cent. P.	5 Lb. P.

Determining Zero Reading on an Ellison Gage

By Herman Bacharach

In the September 1 issue of Chemical & Metallurgical Engineering is a very interesting article by Mr. Evald Anderson on a method of determining the zero reading of an Ellison gage without disconnecting it. The necessity of making this determination is clearly explained and the method is, no doubt, a very good one for portable instruments, but in a permanent installation

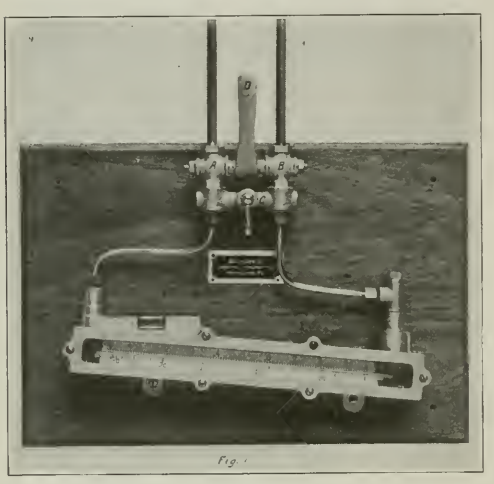

FIG. 1. GAGE READY TO ATTACH THE PRESSURE LEADS

it might be well to make provision for getting the zero reading at any time by using the proper valve and pipe connections instead of rubber tubing and a clamp.

It would probably interest your readers to know of an instrument comprising a gage properly connected and mounted on a board ready to attach the pressure leads, as shown in Fig. 1.

The valves *A* and *B*, Fig. 1, are closed simultaneously by lever *D*, and cock *C* is then opened. The oil will then come to rest at the zero position. After this position is noted, the valves *A* and *B* are opened and cock *C* closed, thus placing the gage in operation. Since the two pressure leads are closed when the zero position is being determined, there is no danger of the differential pressure having any influence on the reading and also, since the operation of these valves is simultaneous, the liquid will not be forced out of the gage. The gage may be calibrated to read velocity or volume.

Fig. 2 shows a scheme of connections where several differential pressures are to be determined. Gages may be used as shown and placed where they may be easily seen by the operators. A recording instrument can be placed anywhere near, perhaps in the superintendent's office, and any one of the differential pressures recorded by the proper arrangement of the link valves *V*. The zero reading of the gages can be taken as described above, Fig. 1.

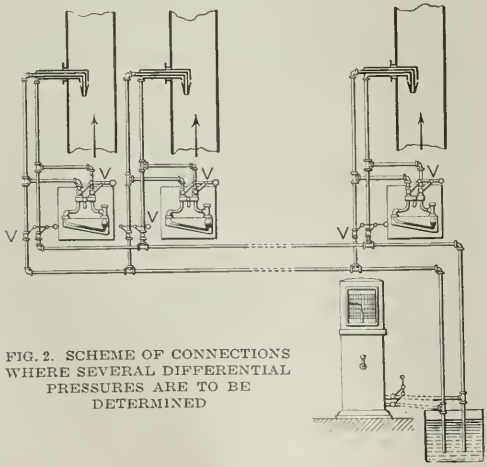

FIG. 2. SCHEME OF CONNECTIONS WHERE SEVERAL DIFFERENTIAL PRESSURES ARE TO BE DETERMINED

Points in Pump Selection*

By B. N. Everett

PUMPS as a rule have very high load factors; that is, ratio of power consumed to maximum demand is high. Also, the power consumption per dollar invested in the apparatus is higher than in most other power-consuming equipment. It would appear, therefore, that the matter of power consumption should be given consideration, especially when the variation of power requirements of different pumping arrangements is so great.

The fact that exhaust steam from direct-acting pumps may often be used to heat feed water has led to the habit of assuming that steam economy is of little importance. But which is the better economy—to use efficient pumps and let water enter the boilers considerably below the boiling point at times; or to allow heat to escape to the atmosphere because of an excess of exhaust steam from inefficient pumps? In the first case the deficiency in feed temperature must be made up by fuel and in the second case fuel is burned to generate the steam that passes through the pumps and heats the feed water and also the steam going to waste.

The word "efficiency" as ordinarily applied to pumps is of little value. For instance, a steam pump with an efficiency of 80 per cent (that is, the indicated horsepower of the water end is 80 per cent of the indicated horsepower of the steam end) was replaced with an electrically driven triplex pump with an over-all efficiency of 70 per cent (that is, the water horsepower was 70 per cent of the horsepower supplied to the motor). The electric pump was driven through the medium of an efficient engine and generator and required only 6 lb. of fuel per 1000 gal. pumped, whereas the steam pump required 42 lb. of fuel per 1000 gal. pumped, which is a difference of several hundred per cent. In this particular case besides the reduction in fuel consumption one man's labor was saved, as the steam was supplied from a separately fired boiler.

The accompanying chart gives the principal points to be considered by an engineer in selecting a pump. No one but an engineer with a knowledge of various classes of pumping machinery and all the individual

*Power, Sept. 24, 1918.

requirements of the plant should handle the matter. The various items are so interdependent that all must be borne in mind while each is considered individually.

The character of the liquid to be pumped has a direct bearing on the size of pipe to use, the advisable speed, the suction lift of the pump and the power required.

CHART SHOWING POINTS TO BE CONSIDERED IN THE SELECTION OF A PUMP

- Liquid to be pumped...
  - Specific gravity
  - Temperature
  - Viscosity
  - Size and nature of solids
- Total head.....
  - Suction lift or head.....
    - Size of pipe
    - Vertical distance
    - Suction-pipe friction
  - Discharge head.....
    - Size of pipe
    - Vertical distance
    - Discharge-pipe friction
- Capacity.....
  - Maximum demand
  - Average demand
  - Storage capacity
  - Breakdown service
  - Hours service per day or per year
  - Advisable speed
  - Source of liquid
- Power.....
  - Available
  - Time of operation
  - Reliability
  - Required
  - Control
  - Estimated cost.....
    - Per 1000 gallons
    - Per month or year
    - Compared to investment
- Cost....
  - Initial
    - Pump
    - Driver
    - Piping
    - Installation.....
      - Location
      - Space required
  - Operating..
    - Labor
    - Power.....
      - Use of exhaust steam
      - Efficiency
      - Transmission losses
      - Cost per 1000 gallons pumped
      - Cost per day or year
      - Fuel consumption
    - Fixed charges

Hot water must flow to the pump under a head. Pumps handling sewage, sand, etc., need special features.

In deciding on the size of pipe to use, each of the following should be considered: Liquid to be pumped, total friction head of pipe and fittings, maximum capacity, average demand, hours service per day, per year, etc., and cost of power. It is a problem of balancing the cost of power consumed to overcome friction against the cost of the line installed. It is somewhat analogous to figuring the size of an electric transmission line. It requires power to overcome friction in proportion to the amount of liquid pumped and the extra first cost of a larger size of pipe will often be returned in saving in power in a short time.

Some time ago data sheets giving the friction of water flowing through pipes and elbows were revised by pump manufacturers because they did not agree with practice. Pipes soon get scaled up inside and offer more resistance than when new.

When a pump is pumping to a system direct, without any storage provided, it must be large enough to meet the maximum demand. Care should be taken that no loss of time is incurred through lack of pump capacity. A woolen mill had a number of machines that required filling with liquid periodically. They were served by a pump that required ten minutes at each filling. It was shown that the output could be increased by reducing this period to two minutes. A pump of the required capacity would have five times the displacement of the old pump, which was of ample capacity to supply the average demand of all machines. So, by installing a storage tank of a capacity to meet the maximum demand the filling period was reduced to less than two minutes. Besides, power was saved by reducing the many starting and stopping periods.

Sometimes two pumps can show better economy than one. A manufacturing plant was using water for all services by pumping from artesian wells to a tower tank under a total head of 120 ft., and the water requirements had outgrown the capacity of the pump. Approximately half of the water was used for cooling gas engines and air compressors in the power plant, for which service a head of 30 ft. was ample. A separate pump and control tank were installed and the power required to pump water was reduced 30 per cent, at the same time increasing the pumping capacity for future requirements.

The calculations of the actual power consumption of a pump should include all the power used or necessarily wasted. The heat lost by radiation and valve leakage in keeping a pipe line and steam pump warm and ready for service often amounts to considerable per 1000 gal. pumped. A belted triplex pump, even with an efficiency of 80 per cent, if controlled by a bypass valve, may be consuming power at its maximum rate and actually delivering only a small percentage of its capacity.

As a general rule direct-acting steam pumps should be employed only where use of all the exhaust steam is possible, or where service is intermittent and better economy will not warrant a larger investment. Steam-valve leakage often amounts to an enormous total, and pump slippage is often a more formidable loss than is suspected. Consider a direct-acting steam pump supplying an average demand equal to 30 per cent of the normal capacity of the pump, pump slippage at normal rate amounts to 15 per cent, and the pump is controlled by a throttling type pressure control valve. Then the slippage (15 per cent of capacity) amounts to 50 per cent of the discharge (30 per cent of capacity) and the steam consumption due to slippage is 50 per cent instead of merely 15 per cent. Under these conditions also the radiation losses and valve leakage amount to more per 1000 gal. pumped. So it is often the case that the power consumption per 1000 gal. pumped is more than double what would be indicated at a normal speed.

Tilting pumping traps are used extensively in handling condensation and feeding boilers, and very low steam consumptions are obtained when pumping hot water. Tests showing steam consumption when pumping cold water would be interesting.

In a certain plant that used a great number of steam pumps, serving evaporators, washers, coolers, etc., the pumps were allowed to run without oil and at destructive speeds and abused generally. Production was interrupted almost daily in one department or another by pump trouble and the pump repairman's hair was gray. The chief engineer said that although he could use the exhaust from the pumps, he was installing single-stage centrifugal pumps direct-connected to electric motors in every case where they could be applied, simply because they are more fool-proof and increase the factor of safety against interruption of service.

In the case of centrifugals even greater care should be taken in making the application, especially in regard to the correlation of total head and peripheral speed of impeller to the motor speed, and the means of regulating capacity.

Recent Chemical and Metallurgical Patents

Magnesian Furnace Refractories

Magnesium Oxide from Dolomitic Rock.—A. M. MITCHELL of Tuckahoe, N. Y., patents a process of separating magnesium oxide to be used in the manufacture of refractories from mixtures of magnesium and calcium carbonates commonly called dolomitic rock. The ground rock is charged into a tube mill, set into a furnace and heated externally to about 950 deg. F., at which the CO_2 is driven off from $MgCO_3$, but which is too low to decompose the $CaCO_3$. During calcination the material is finely ground, thus separating the minute particles of magnesite and calcite. After calcination the calcite remains in its original shape, crystalline and compact, while the magnesite has been converted into MgO, which is powdery and light. Separation of these two materials may then be effected by well-known gravity concentrators. (1,273,110; assigned to Mitchell & Grenelle; July 16, 1918.)

Furnace Lining.—S. R. NEWBERRY of Cleveland, Ohio, patents the following method of burning dolomitic limestone in order to prepare a refractory material which will not air-slack. He takes a dolomitic limestone as free as possible from silica, and wet-grinds to 100 mesh together with from 2 to 5 per cent of bauxite, iron ore or some substance containing oxides of the aluminium-iron group. These amphoteric bases form very fusible compounds with the lime, and but a small percentage is required to properly "fix" the lime so that it will not form hydrates. The slurry is burned at from 2700 to 3000 deg. F. in a cement kiln, the temperature depending upon the nature and quantity of the addition, and the resulting clinker crushed to required size for sale or for the formation of refractory brick. (1,267,686; May 28, 1918.)

J. O. HANDY and R. M. ISHAM of Pittsburgh, Pa., produce a furnace lining material from dolomitic or magnesian limestones in somewhat the same manner. Their fluxing agent is calcium chloride, or in case the material is nearly pure MgO, magnesium chloride is better. Preferably the crude material, crushed to 20 mesh, is mixed with sufficient brine or bittern so that the dried material will contain about 10 per cent of the chloride. This is then dried to a coherent mass and burned in a rotary kiln at 1500 deg. C. During this operation the chloride decomposes if sufficient water vapor is present from the products of fuel combustion or otherwise and forms hydrochloric acid which passes off with the furnace gases. The resulting clinker contains but fractional percentages of chlorine, and is available for making furnace linings or refractory bricks. (1,270,818; assigned to A. S. Davison Co.; July 2, 1918.)

Artificial Magnesite.—J. O. HANDY and R. M. ISHAM of Pittsburgh, Pa., prepare an artificial magnesite claimed to have the desirable refractory qualities of imported crude magnesites. They calcine a dolomite in a rotary kiln so as to remove all the carbon dioxide without "dead burning." The calcine, granulated to the size of a pea, is leached with cold water to remove the calcium oxide down to from 3 to 10 per cent. Additions of basic slags and clays are then made and the material is re-burned at 1550 deg. C. to remove the water of hydration and carbon dioxide. The final product should have 85 to 88 per cent MgO, lime 3 to 10 per cent, silica 4 to 8 per cent and a little iron and alumina. The small amount of lime is necessary for bonding, yet is so small that danger from slacking is absent. (1,270,819; assigned to A. S. Davison Co.; July 2, 1918.)

High-speed Steel Substitutes.—P. R. KUEHNRICH of Sheffield, Eng., notes that cobalt has been used as an ingredient of many alloy steels and that carbon-chromium steels are known to be much superior to plain carbon steel tools, although they do not possess the quality of red-hardness until cobalt is added, which fact constitutes his invention. He recommends a composition approximating

C	1.5 per cent
Cr	12.0 per cent
Co	3.5 per cent
Si	0.3 per cent
Mn	0.2 per cent

with up to 1 per cent of any of the other metals of the chromium group. (1,277,431; Sept. 3, 1918.) G. L. KELLEY and A. H. MILLER of Germantown and Ambler, Pa., claim especial toughness as well as hardness by the addition to nickel of from 0.5 to 2 per cent of zirconium, which is less than previously recommended, when accompanied by aluminium and silicon. The sum of the last two ingredients should be at least 8 per cent; they are equivalent to a certain extent, but the content of aluminium or silicon should not fall below 2 per cent or go above 8 per cent. (1,258,227; Mar. 5, 1918; assigned to Midvale Steel Co.) H. S. COOPER of Cleveland, Ohio, patents a composition very similar to the above. He presents diagrams showing that at least 10 per cent aluminium must be added to nickel to give a scleroscopic hardness greater than 55, which is necessary for a cutting tool. More aluminium, while increasing the hardness, cuts down the already deficient toughness. Another diagram shows that if 2 or 3 per cent silicon be added to the Al-Ni alloy, the hardness is still sufficient, while the grain is finer, and the toughness increased. Adding from 1 to 15 per cent zirconium to the ternary alloy gives the mixture red-hardness and great toughness and forms an excellent cutting tool. Chromium group metals may be added to the quaternary alloy with advantage—tungsten especially increases the life of the tool. These alloys melt at a low temperature and can be cast to shape and ground into a tool. No heat treatment is required. The alumino-thermic method of reduction of the constituent oxides is recommended for the production of the pig metal. (1,227,046, Aug. 27, 1918, and 1,278,304, Sept. 10, 1918; assigned to the General Alloys Co.)

Manufacture of Acetic Acid.—HENRY DREYFUS of Basel, Switzerland, patents processes of making acetic acid, which comprise passing a mixture of acetaldehyde and oxygen over a catalyst at a temperature between the boiling point of acetic acid and 400 deg. C. (1,286,255-1,286,256).

Ferro-molybdenum Manufacture.—E. H. WESTLING and CARL ANDERSON of San Francisco patent the process of making ferro-molybdenum from ferric molybdate by reducing the latter with carbon or hydrogen at a comparatively low temperature (less than 900 deg. C.), producing a spongy product which does not oxidize easily, and which is assimilated in a steel bath with the utmost facility. The ferric molybdates may be precipitated from soluble alkaline molybdates by ferric sulphate or from soluble molybdenum salts by the same reagent after neutralizing the solution with alkaline carbonates. With a minimum of iron, a yellow $Fe_2(MoO_4)_3$ is formed, while with excess a brown $Fe_2O_3 . MoO_3$ results. By properly mixing the two a ferro with any desired composition between the limits may be produced. (1,278,408; Sept. 10, 1918.)

Ferro-phosphorus and Cupro-phosphorus.—H. A. WEBSTER of Columbia, Tenn., finds that if a proper mixture of iron phosphate, coke and limestone is heated to from 1000 to 1500 deg. C. in a rotary kiln, the interior of the furnace becomes lined with incandescent carbon which materially hastens the reaction. The products—an iron phosphide containing 25 per cent phosphorus and a slag—may be granulated and separated by a magnetic separator. The gasified phosphorus may be largely retained in the nodular phosphide by charging iron filings with the mixture. The proportion of phosphorus in the compound may be increased to 30 per cent by heating the same mixture in a closed furnace at three atmospheres, cooling the melt under pressure to the liquidus and then tapping the contents. (1,264,236 and 7; April 30, 1918.) L. A. JEFFS of Salt Lake City, Utah, patents the process of making cupro-phosphorus in a furnace similar to the Stassano. He charges phosphate rock, oxidized copper ore and a large excess of carbon, together with the necessary flux. The reduced copper trickles down through incandescent carbon against an upward stream of phosphorus and CO, and the cupro-phosphorus formed collects in the crucible below the slag layer. By using a small percentage of copper the exit gas can be made so rich in phosphorus as to warrant its recovery as the principal product. (1,268,849; June 11, 1918.)

Ferro-silicon.—J. E. JOHNSON, JR., of Hartsdale, N. Y., notes that the large amounts of nitrogen in atmospheric air lowers the maximum temperature in the ordinary blast furnace to a point where a 12 per cent ferro-silicon is the ordinary alloy made. Since the calorific intensity varies approximately inversely as the products of combustion, he claims that the temperature of the focus obtainable with air enriched to 50 per cent oxygen will be high enough so that much larger amounts of silicon will be reduced and a 50 per cent alloy equal to that now produced in electric furnaces will result at a lower cost. Enriched blast will also reduce the cost of the lower grade alloys. (14,547; Reissued Nov. 12, 1918.) GEORGE C. FURNESS of New York notes that the electric shaft furnace with deeply embedded electrodes ordinarily used in commercial production of ferro-alloys requires a charge which at once shall have a low electrical conductivity and a high porosity. In the manufacture of ferro-silicon, which consumes a large proportion of reducing carbon, this material, ordinarily introduced as coke, anthracite or charcoal having a high specific conductivity, tends to short circuit the electrodes along their adjacent sides if charged in sizable lumps. If, however, the carbon is finer, it makes a dense charge which prevents ready escape of the gaseous products of reaction. He therefore patents the use of from 20 to 40 per cent of the total carbon requirements in the form of small-lump bituminous coal, which has a low conductivity and whose evolved gases burning at the top of the shaft minimize the heat losses at that region. (1,284,645; Nov. 12, 1918; assigned to Electro Metallurgical Co.)

Potassium Sulphate From Alunite.—H. F. CHAPPELL of New York City patents the method of separating potassium sulphate from calcined alunite shown in the diagram, Fig. 1. The method depends upon the fact that the sulphate is more than twice as soluble in water at 100 as at 20 deg. C. The boiling solutions in the dissolver are maintained at that temperature by heating make-up liquors in the heat interchanger just after the muffle furnace, as well as by the addition of hot calcine directly into the tank. The filtered hot solutions are passed through a cooling tower against a countercurrent of air, and the crystal bearing mother liquor centrifuged and returned to the dissolver. Evaporation and other losses are made up with wash water from the alumina filter. (1,268,433; assigned to Mineral Products Corporation; June 4, 1918.)

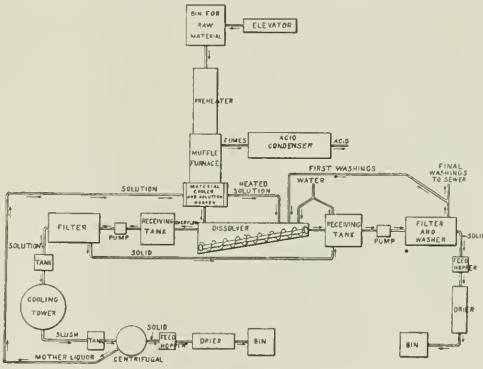

FIG. 1. FLOW SHEET ILLUSTRATING METHOD OF SEPARATING POTASSIUM SULPHATE FROM ALUNITE

Personal

MR. J. CORBUS BUSHNELL, formerly associated with the Business Men's Clearing House, Chicago, Ill., and until recently connected with the U. S. Employment Service as special agent to examine the personnel methods in vogue at Vickers, Ltd., and Woolworth Arsenal, England, has been engaged by the General Engineering Agency, Pittsburgh, Pa., as personnel director.

MR. H. L. GREENE has been appointed chief metallurgist of the Willys-Overland Co. of Toledo, Ohio, and its allied companies.

MR. J. O. LEWIS, superintendent of the petroleum experiment station at Bartlesville, Okla., has just been appointed chief petroleum technologist of the Bureau of Mines, Department of the Interior, in place of MR. CHESTER NARA-

MORE, who has resigned from the Government service to join the Union Petroleum Co., with headquarters at Philadelphia, Pa. Mr. Lewis will be succeeded at Bartlesville by Mr. W. P. DYKEMA, petroleum engineer of the bureau.

MR. SCOTT LINTNER of San Francisco is now manager of the Ray-Broken Hill Mines at Ray, Ariz.

MR. EDWARD A. MILLER has been appointed as assistant superintendent of the Jersey City plant of the Metal & Thermit Corporation, New York, N. Y. Mr. Miller was one of the pioneers in autogeneous welding and cutting, having established the first oxy-acetylene shop in New York City early in 1908 under the corporate form of the Acetylene Welding Co.

MR. JOHN F. NEALIS, who recently received his discharge from the Aero Observers' branch of the service, is now associated with the Powdered Coal Engineering & Equipment Co. of Chicago as advisory engineer. Mr. Nealis formerly had charge of research work for the U. S. Steel Corporation.

MR. D. A. O'CONNELL has been appointed manager of the Seattle office of Marden, Orth & Hastings Corporation.

MAJOR W. P. PUTNAM of the Ordnance Dept., U. S. A., has returned to Detroit to resume his activities as president and general manager of the Detroit Testing Laboratory.

MR. CHARLES F. QUAINTANCE has retired as secretary and sales manager of the Herold China and Pottery Co., Golden, Colo.

MR. W. S. QUIGLEY, president of the Quigley Furnace Specialties Co., Inc., sailed for Liverpool on the Baltic Feb. 15. He will spend several weeks in England, France and Italy.

MESSRS. J. F. SCHOELKOPF, C. P. HUGO SCHOELKOPF and J. F. SCHOELKOPF, JR., have withdrawn as directors of the National Aniline & Chemical Co., New York, N. Y.

MR. C. C. WALLACE, formerly manager of loading of munitions section of the Stenotype Co., Indianapolis, Ind., is now director of development and service, Powdered Coal Engineering & Equipment Co., Chicago, Ill.

MR. FRANK E. WICKS, consulting engineer, recently resigned as superintendent of mills for the Chino Copper Co. at Hurley, N. M., and has opened an office at 404 Union Oil Bldg., Los Angeles, Calif., where he will specialize in concentration and flotation, crushing and fine-grinding problems and plant management.

MR. HARRY W. WOLFF has recently resigned as general manager of the Rector Chemical Corp., N. J., to take charge of the chemical engineering research laboratories of Dr. Alcan Hirsch, New York City.

Obituary

MR. JAMES H. ALEXANDER, for many years one of the vice-presidents of the Standard Oil Co. before its re-organization, died Tuesday, Feb. 18, at his home in Elizabeth, N. J. He was one of the pioneers in the development of the oil industry in the United States and was closely associated in business with John D. and William Rockefeller, H. H. Rogers and the late H. M. Flagler. Mr. Alexander was born in Toronto, Canada, 84 years ago. He is survived by his widow and three sons.

MR. ERNEST L. GODBE, of Salt Lake City, Utah, died at Bath Lake, Calif., Jan. 16. He specialized in chemistry and metallurgy and for many years was engaged in mining in the Pioche, Nev., district, having been vice-president of the Prince Consolidated Mining & Smelting Co. up to a few years ago. He was 51 years old.

MR. FRANK MORRIS BAUM, retired vice-president and general manager of the Portland Wood Pipe Co., who for eight years was State Senator for Spokane County, Washington, died on Feb. 4 in Pasadena, Calif. Mr. Baum was an associate of the gentlemen who are now the controlling factors of the Continental Pipe Mfg. Co. of Seattle and Portland.

Current Market Reports

The Non-Ferrous Metal Market

Friday, Feb. 21.—No response is being made to liberal price concessions, and producers are beginning to curtail production.

Aluminium:—After March 1 aluminium will be on an open market. That prices will go down is evidenced by sales being reported at from 30c. to 32c. per lb., but a rapid return to prewar prices is not expected. Sheets, 18 gage and heavier, are 42c. Powder, 100 mesh, 70c.

Antimony:—Antimony is in light demand and prices have declined to 7¼c. per lb.

Copper:—Copper has been offered as low as 16c. per lb., but there is no immediate consuming demand and buyers are holding off.

Copper sheets, hot-rolled	lb.	$0.24½—$0.34
Copper sheets, cold rolled	lb.	.25½— 23.
Copper bottoWs	lb.	.37 — .33½
Copper rods	lb.	.21½— ....
Copper wire	lb.	.19½— ....
High brass wire and sheets	lb.	.20½— .26½
High brass rods	lb.	.19½— .25½
Low brass wires and sheets	lb.	.22½— .28½
Low brass rods	lb.	.23½— .29½
Brazed brass tubing	lb.	.31½— .37½
Brazed bronze tubing	lb.	.36 — .42½
Seamless copper tubing	lb.	.31 — .37
Seamless bronze tubing	lb.	.31 — ....
Seamless brass tubing	lb.	.30 — .36
Bronze (gold) powder	lb.	1.00 — 1.75

Lead:—Five-cent lead has stimulated buying, with a result that prices have gone up to 5.1 to 5.2c.; Sheets, 8c. lb.

Tin:—The U. S. Steel Products Co. has liquidated over half of its 10,000-ton allotment at 72½c.

Zinc:—Spelter has been steadier than usual, showing only a 50c. drop per ton during the last two weeks. New York spot $134.50 and spring futures $127.50 per ton.

OTHER METALS

Bismuth	lb.	$3.20 — $3.65
Cadmium	lb.	1.40 — ....
Cobalt	lb.	2.50 — 3.50
Magnesium	lb.	1.75 — 2.10
Mercury	75 lb.	85.00 — ....
Mercury	lb.	1.95 — ....
Nickel	lb.	.40 — .45
Tungsten	lb.	Nominal
Iridium	oz.	175.00 — ....
Palladium	oz.	115.00 — ....
Platinum	oz.	100.00 —105.00
Silver	oz.	1.01½— ....

The Iron and Steel Market

Production of steel ingots during January was at the rate of about 41,700,000 gross tons a year, this being about 85 per cent of capacity, which may be estimated at 49,000,000 tons per annum. The January rate was 3.8 per cent under the average rate in November and December and about 10 per cent under the maximum rate ever attained, which was in September, 1918, about 46,800,000 tons.

The rate of production has been declining continuously since just before the Christmas holidays. No close estimate for the month of February can be made, but the monthly report will probably show something in the neighborhood of 75 per cent for the month. The month closes with a rate much below the opening rate.

Mills have operated at widely divergent rates. Some large mills have operated almost full, others ran at 50 to 75 per cent, while a number of small plants have been closed entirely. The divergences are due largely to the character of business the different mills commonly seek, as many small mills depend upon transient orders. This serves them in good stead on a rising market, as they obtain the advantage of price advances more promptly than the mills that book far ahead, but in times like these the policy is disadvantageous.

OPERATIONS IN DETAIL

On the whole, the sheet industry is probably operating at the best rate for any branch of the finished steel trade. The leading interest has been operating at about 80 per cent, while the independents have been doing about 70 per cent. In the case of tin plate there is the curious divergence that the leading interest has been operating at practically 100 per cent in the past fortnight, while the independents have not averaged more than about 50 per cent. The pipe mills show an average of 70 or 75 per cent, doing quite

well in the lap weld departments but rather poorly at butt weld furnaces. Wire mills are averaging 50 to 60 per cent, while plate mills are doing about the same and structural and rail mills are doing hardly anything.

The percentages of finishing capacity in operation as here estimated do not average nearly as high as the estimated percentage of steel production in proportion to steel making capacity, that being due to the simple fact that the finishing capacity of the industry materially exceeds the steel-making capacity, and this is a necessary alignment, otherwise the steel-making departments never could operate in full, as demand could not be expected to be distributed among the different finishing departments in the precise proportions required by their respective capacities.

No Investment Buying

The character of steel demand as shown by the proportions of various finished steel products lately called for is in strict conformity with what would be expected from a scrutiny of the industrial and economic situation. There is demand for steel that enters into common everyday use, while there is practically no demand for steel that enters into construction work. That is to be expected. The investment buyer has not acted. There are scarcely any building projects. The Bridge Builders' and Structural Society reports that the bookings of fabricated steel jobs in January represented 12 per cent of the month's capacity, this breaking the previous low record of 20 per cent, made in November, 1914.

Petroleum is not over-plentiful, the world's prospective requirements are heavy and new wells must continuously be brought in to maintain the country's production, hence it is not strange to find that in the tubular goods industry the most active branch is that of oil country goods. Standard steel pipe, particularly in butt weld sizes, is in very poor request, as it enters chiefly into building operations. A little business has been done in small lots of line pipe, and several large oil and gas interests have indicated to pipe mills that they are willing to go ahead with the laying of some large pipe lines, if they are permitted to buy at certain prices, these prices being only about 10 to 20 per cent below current quotations, so that here at any rate is a case of "the investor" naming his terms, and in substance actually making a bid. Generally speaking the investment buyer is not in the market and has not made up his mind as to the precise conditions he would require in order to bring him in.

The steel demand from the automobile trade is excellent, practically up to the highest level of the past. The automobile shops are not yet up to full production, but are rapidly being swung into line, and the makers are confident that before the end of the year they will be producing automobiles at a greater rate than ever before. They seem to be certain of their market and they are not particularly contentious as to prices to be paid for steel.

Prices to Decline

There is scarcely any doubt that finished steel prices will experience a very substantial decline by April 1. The reasoning is quite simple. Broadly speaking, there are two general classes of buying, that for current requirements and that for investment, or for construction work. The end of the war found it that the investment buyer was not ready to act and would hardly be ready until settled conditions throughout the world should become assured and prices of material and cost of labor should come down. There was no particular occasion, therefore, to consider the investment buyer in the matter of steel prices. He would not act even with a wholesale reduction. The current buyer might, however, be expected to buy in moderate fashion because he could not wait, and in keeping with this idea slight price reductions from the Government limits were made last December, averaging about $4 a ton on all products. It was thought at the time there might be another reduction of perhaps equal amount on April 1, in keeping with the quarterly consideration of prices practised by the War Industries Board during the period of control.

Developments of the past few weeks, however, have shown that even the transient or current buyer will not take hold to any extent at these prices. He has remarkable powers of staying out of the market, and he is greatly helped in this conduct by the fact that the mills can roll and ship material almost instantly on a new order. The need for maintaining stocks, on the part of the jobber and manufacturing consumer, is almost eliminated. In the late months of the war these buyers were complaining of inadequate stocks, in many cases, but the stocks were appraised according to the needs of the time, when mill deliveries were very uncertain.

Thus even the transient or everyday buyer has been failing the steel industry, and it is necessary to bring him in. Hopes have been entertained that there would be a spring buying movement of at least moderate proportions, but it appears that even that must be stimulated by price concessions. It is practically certain, therefore, that in the near future rather extensive reductions in steel prices will occur. While the steel trade is not permitted to meet and agree what it shall do, it has a spirit of following leadership, recognizing that it is necessary to have precise prices to which to adhere or utter market confusion would result. While the Steel Corporation frequently takes the lead, the prospect is that the prospective decline will be led by one of the independents, which will announce reduced prices, the other producers thereupon adopting these prices, whatever they may be. There are no definite predictions as to the size of the prospective declines. The lowest guess is that merchant steel bars will be put at 2c., from their present level of 2.70c., the Government limit having been 2.90c. That would make the reduction $14 per net ton, but it would leave bars at $12 a ton above the average of quotations in the ten-year pre-war period 1904 to 1913 inclusive. Billets in that event would probably strike around $35, with sheet bars perhaps $2 higher, and the merchant furnaces might find $25 a convenient price on which to make their fresh stand, basic being now $30 furnace, and foundry $31.

The Chemical Market

Coal-Tar Products:—While there has been no unusual volume of business noted for coal-tar products, little has developed in the way of price changes, in addition to the general list that has already been revised. Most all producers are anticipating a return to normal conditions in the trade, but, according to most reports, there is not much likelihood of any great resumption of business before the latter part of next month. Among the crude products, phenol maintains the unsettled position that has been in evidence during the recent period, while benzol is subject to a sufficient call to take the slack off the market. Some of the items are being offered in rather liberal quantities and most trading seems to be through first hands, who, for the most part, are not disposed to make any concessions to stimulate business, despite the fact that, in some instances, material is being offered through second hands somewhat below the manufacturers' prices.

Phenol:—Cheap offerings of this product seem to constitute the only activity and sales are noted as low as 8¼c., drums included. In the aggregate, a large volume of business is evident, many manufacturers having discontinued the production, as quantities of the product are offered at prices considerably below the cost of manufacture.

Benzol:—Occasional lots of this commodity reach the resale market at prices ranging from 2c. to 3c. below the manufacturers' prices. However, the market is seemingly well maintained so far as prices are concerned and is generally regarded as steady.

Toluol:—Supplies of this material are none too freely offered by second hands, and when lots of the product are offered at prices below that of the producers, there is some interest generally noted on the part of buyers. Manufacturers are firmly maintaining their prices and report a fair volume of business passing.

Naphthaline:—The consumers of this product seem to be confining their attention along conservative buying, while in the resale market a fair volume of business is passing and this is generally transacted at price conces-

sions. First hands, however, have made no price changes for the various grades of this product.

Cresylic Acid:—Foreign competition has seemingly not affected the situation up to the present and prices for this product are subject to no material change. The current call is of no pronounced volume, although sufficient trading is passing to take the slack off the market.

Paraphenylenediamine:—This material is one of the coal-tar products that has maintained a steady position in the market, and while buying seems to be confined to small lots, a satisfactory business is generally noted. The various producers continue to quote on the former basis.

Dimethylaniline:—The sales for this material are of a minor character, and the recent decline in prices has seemingly had no effect in stimulating business. Buying is conducted along conservative lines, with stocks more than sufficient for the current call.

Dinitrophenol:—A satisfactory business is reported to be passing for this product, although in most directions there seems to be an accumulation of stocks, but prices remain unchanged at the recent decline.

Diphenylamine:—There has been some little trading in this comomidity at the recent decline in prices, but for the most part individual sales are of a minor character.

Beta Naphthol:—Local trading assumes a quiet attitude and there is an absence of anything like a normal demand; however, some factors have received inquiries for the product for export purposes and it is expected that consumption in this direction may bring about a more favorable condition. Quotations generally offered are continued on the former levels for the various grades.

Monochlorbenzol:—While there is the regular consuming trade in evidence, individual sales are in small lots and stocks are fully in accordance with the current call. Second hands are unable to offer material at concessions and manufacturers are firmly maintaining prices.

Paranitraniline:—The business passing in this commodity is of no unusual volume and the extent of the recent reduction in prices does not seem to be sufficient to be attractive to buyers. Stocks of the product in the various directions seem to be accumulating, which appears to be of some concern to producers.

HEAVY CHEMICALS:—The tone of the heavy chemical market continues to reflect a feeling of uncertainty with the majority of the consuming buyers, while on the other hand trading in many of the items under this heading has been somewhat more active, and now that the holidays are over, which undoubtedly has had its effect, most operators are looking forward to a more active market. Export trading, up to the present, has been in no pronounced volume, although the general outlook is quite favorable. While there has been no general decline in prices, trading among second hands was subject to keen competition, which resulted in concessions in some instances, but in the aggregate the volume of business was not of such proportions to effect any radical changes. Soda ash and caustic soda, the products of considerable interest, maintain a rather weak position in the market and both buyers and sellers are confining their attention along quiet lines.

Soda Ash:—While there has been an absence of important price fluctuations during the interval, trading was not sufficiently active to affect the situation one way or the other. Sales of bag ash from the warehouse were consumated at $1.40 per hundred lb., with barrel ash selling at $1.75 ex-store. Light ash in bags was generally offered at from $1.75 to $1.85, while movement in double bags was particularly quiet, and for this material at Middle Western shipping points prices range from $2.15 to $2.25. Dense ash in single bags was quoted at $3.25 to $3.30 ex-store in New York, while in Philadelphia, $3.60 was asked. Double bags at the same shipping point were held at $3.10, with 3c. the general quotation at Painsville.

Caustic Soda:—Quiet trading seems to have been the feature during the past two weeks, and at periods weak holders played havoc with the market and sales for ex-warehouse material were noted at $2.75. However, for the most part, prices were fairly well maintained despite the quiet conditions. It was rather difficult to do better than $2.85 per hundred lb. at the close for resale material, while others were holding at $2.95 and $3.05, but manufacturers displayed no disposition to make any effort to meet this situation.

Bleaching Powder:—The market for this commodity continues to be quiet, with local trading confined to small lots, and while purchasing for export purposes has been of no pronounced volume, a fairly active movement in this direction is noted. There were offerings at the close, by second hands, of large domestic drums at 1½c. per lb. works, while manufacturers were quoting 2c. Material in small export drums for immediate shipment from works was offered at 2¾c. f.a.s. while the large drums were available at 2½c. f.a.s.

Copper Sulphate:—Despite the fact that manufacturers have lowered their prices for this commodity to $7.90 per hundred lb. there were offerings through second hands at $7.80 for the large crystals 99 per cent. Further reductions are not generally anticipated and business seems to be steady, but individual sales are for no important quantity and would indicate buying is conducted along conservative lines.

Cyanide of Soda:—The production of this chemical is confined to a few quarters and prices are firmly maintained, although business is of a routine nature, with the demand by no means pressing. The 96-98 per cent material is held at 30c. to 31c., while the chloride mixture of 73-76 per cent is quoted at 25c. to 27c. and the chloride carbonate mixture is offered at 20c. to 21c.

Sulphate of Alumina:—While supplies of this product are none too freely offered in the market, the consuming demand in proportion is not strong and no difficulty is experienced in meeting the situation. Prices are firmly maintained in most directions, with the iron free being held at from 3¼c. to 3¾c. per lb., while the commercial grade is quoted at 2⅜c. to 2¾c. ex-store.

Bicarbonate of Soda:—The commodity is easier and there have been some fractional declines in prices. For instance, there were resale offerings of barrel material at $2.65 per hundred lb., but manufacturers are not inclined to shade their recent quotations of $2.75.

Silicate of Soda:—A fair volume of business is noted to be passing for this material, but factors of the product report stocks in sufficient quantity to take care of additional business. The 40-degree variety seems to be somewhat easy in supply and was offered at from 2¼c. to 2⅜c. per lb. ex-warehouse, while the 60-degree product seems to be more scarce and is quoted at 4¾c. to 5c. ex-store.

Sodium Sulphide:—Local trading continues along quiet lines, while some business is passing for export purposes and prices are steady. The 60 per cent fused variety is held at 4¾c. to 5c. ex-store, while the 30-32 per cent crystals are quoted at 2⅝c. to 3c. per lb.

Bichromate of Soda:—No material improvement can be traced in this market; sales during the past week were noted as low as 12¼c. This, however, is not generally regarded a market figure with quotations at the close ranging from 12½c. to 13c.

Bichromate of Potash:—The demand for this product has been of sufficient volume to keep the spot situation well sold up and the market is in such a condition at the moment that it is rather difficult to locate spot material. The various operators are quoting 37½c. to 38½c. for material to be delivered in about ten days.

Hyposulphite of Soda:—The pea crystal product, which is the most preferable, is seemingly none too free in supply, although the spot situation, at most times, is fully in proportion to the current call. Prices are firm at from 3½c. to 3⅝c. per lb. ex-store.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET FEB. 21, 1919

Acetic anhydride	lb.	.90	—	1.00
Acetone	lb.	.15½	—	.16
Acid, acetic, 28 per cent	cwt.	3.25	—	3.50
Acetic, 56 per cent	cwt.	6.50	—	6.75
Acetic, glacial, 99½ per cent, carboys	cwt.	14.00	—	14.50
Boric, crystals	lb.	.13½	—	.15

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Arizona

AGUILA—The Bullard Mining Co., Wickenburg, will build a new leaching plant at its properties here.

BOUSE—The Arizona Desert Mining & Milling Co., Bisbee, will install two ball-mill units supplementing 20-ton mill now on ground and operated. J. H. King, superintendent.

Colorado

EUREKA—The Empire State Mines & Reduction Co., will build a 50-ton unit of the 100-ton concentrating mill near here, and is in the market for lumber, crushers, rolls, classifiers, concentrating tables, pulleys, belting, meters, roofing, pipe, etc. Estimated cost, $25,000. W. Akers, superintendent.

Connecticut

HARTFORD—The city will build a slow sand filtration plant, consisting of eight half-acre filter beds and a 40 x 40 ft. laboratory building. Address Chief Engineer, Hartford Water Works, Room 702, Pilgard Building.

Georgia

SAVANNAH—The Southern Fertilizer & Chemical Co., American Bank & Trade Building, will rebuild its plant, recently destroyed by fire, entailing a loss of $225,000.

Idaho

BONNERS FERRY—The Cyanide Gold Mining Co., recently incorporated with a capital of $3,000,000, has taken over the property of the Deer Creek Gold Mining Co., near here and will develop same. Plans include the construction of a large cyanide plant.

CALDWELL—The School District is having plans prepared by Wayland & Fennell, architects, Idaho Bldg., Boise, for the construction of a two-story, concrete high school building. Plans include the installation of a chemical laboratory and scientific rooms. Total estimated cost, $75,000.

NAMPA—The city will build a 700,000-gal. disposal plant in connection with the new sewerage system. L. R. Cook, City Hall, engineer.

PINE CREEK—The Nabob Consolidated Mining Co., Kellogg, will build a new concentrating plant at the works here. Estimated cost, $50,000. H. C. Barnett, Kellogg, manager.

Illinois

EAST ST. LOUIS—The Obear-Nestor Glass Co., Broadway and Belt Line R.R., has awarded the contract for the construction of a two-story, 82 x 192 ft. glass factory, to Keeley Bros., Belt and State Sts. Estimated cost, $65,000.

ROCK PARK—The Rock Falls Box Board Co. will build a three-story, 120 x 135-ft. factory and is in the market for equipment for same. Total estimated cost, $130,000. J. L. Carey, 208 North Laramie Ave., Chicago, engineer.

Kentucky

OWENSBORO—The Glenmore Distilleries Co. will build a distillery for the manufacture of alcohol.

Maryland

BALTIMORE—The Liberty Yeast Corporation, incorporated by J. Bannister Hall, 609 Calvert Building, and associates, with $3,000,000 capital, has acquired the Monumental Distillery at 11th and O'Donnell Sts. and will remodel and equip same for the manufacture of yeast and its by-products.

CANTON (Baltimore P. O.)—J. M. Jones, 1621 Park Ave., Baltimore, and associates, have acquired a site on 5th Ave., and will build a tin manufacturing plant. Estimated cost, $500,000.

HYATTSVILLE—The Washington Suburban Sanitary District is having plans prepared by R. B. Morse, engineer, 324 North Charles St., Baltimore, for impounding the waters of Patuxent, Little Patuxent and Middle Patuxent Rivers to develop water supply. Project includes the construction of a rapid sand filtration plant, etc. Estimated cost, $2,500,000.

Michigan

DETROIT—The Board of Education will develop the laboratory in the Central High School building, Cass and Warren Aves., cost $47,160; equipment for same, $2500; filtering and sterilizing equipment for swimming pool in Cass Technical High School, $10,700.

DETROIT—The Water Board has recommended the City Council to build a complete filtration plant. Estimated cost, $5,326,000. G. H. Fenkell, chief engineer.

HOLLAND—The DePree Chemical Co., 133 West Washington St., Chicago, Ill., will build a chemical plant here.

PONTIAC—The City Clerk will receive bids until June 1 for the construction of a sewage disposal plant, including Imhoff tanks and trickling filters. Estimated cost, $300,000. H. H. Barnett, City Hall, engineer. Noted Feb. 1.

RIVER ROUGE—The Semet-Solvey Co., Milton Ave., Syracuse, N. Y., will build a 50 x 150 ft. acid washing machine house here.

Missouri

CARROLLTON—The Water, Light & Transit Co. will install a modern water filtering system and make other improvements to its property. S. J. Jones, Carroll Exchange Bank Bldg., president.

JOPLIN—The Texas Mining & Milling Co. will install a complete 150-ton mill and is in the market for a hoisting engine, blower engine and derrick boiler. Estimated cost, $25,000. E. D. James, manager.

Minnesota

WASHINGTON—The Directors of the Southwestern Minnesota Sanitarium have awarded the contract for installing a filter plant here, to W. Danforth, Germania Life Building, St. Paul. Estimated cost, $13,660.

Montana

NEIHART—The Cascade Silver Mines & Mills will install a concentrater and trams and is in the market for machinery necessary for the repair and upkeep of same. Estimated cost, $300,000.

Nebraska

OMAHA—The State Legislature plans to appropriate $40,000 for electrical apparatus, laboratory equipment, etc. J. Latenser & Sons, 632 Bee Building, architect.

New Jersey

CAMDEN—J. Evansen & Son, Delaware Ave. and Pennsylvania R.R., will rebuild its soap factory, recently destroyed by fire, and is in the market for machinery for same, including drying and molding machinery, belts, conveyors, heating bags, dry kilns etc. Estimated cost, $150,000.

ELIZABETH—The United States Leather Co., 356 Magnolia St., has awarded the contract for the construction of a two-story, 115 x 220 ft. factory, to the Turner Construction Co., 244 Madison Ave., New York City. Estimated cost, $200,000.

KEARNY—Swift & Co., 32 10th Ave., New York City, N. Y., will rebuild its fertilizer works, boiler plant, etc., here, recently destroyed by fire, entailing a loss of $150,000.

NEWARK—Elmer & Amend, 13-17 Margaretta St., has awarded the contract for the construction of an addition to its chemical plant, to Anthony Imhoff, Inc., 248 West 18th St., New York City. Estimated cost, $3500.

NEWARK—Kelly & McLaughlin, 93 Colder St., will build an addition to its plant for the manufacture of leather. Estimated cost, $8000. A. Peter, 828 Broad St., architect.

New York

NEW YORK—The Commissioner of Water Supply, Gas & Electricity, Municipal Bldg., has awarded the contract for furnishing and delivering liquid chlorine, to the Hooker Electrochemical Co., 40 Wall St., $7955; chloride of lime, to Arnold Heffman, Providence, R. I., $1094, respectively. Noted Feb. 15.

POUGHKEEPSIE—The State Hospital Commission, Capitol, Albany, received bids Feb. 11 for building intake crib in the Hudson River, thence to filters, installing new filters, also changing water mains and reservoir at the Hudson River State Hospital, here, from C. R. Simpson, 90 West St., New York City, $57,887; H. E. Fox Construction Co., 81 East 125th St., New York City, $58,000; New York Sewage Disposal Co., 37 East 28th St., New York City, $62,997. Noted Feb. 1.

Ohio

IRONVILLE—The Paragon Refining Co., 2935 Front St., Toledo, will build a refining plant here. Estimated cost, $100,000.

Oklahoma

MIAMI—The Alexander Lead & Zinc Co. will build a mill and develop property here. Estimated cost, $75,000. G. M. Ramsey, superintendent.

Oregon

ASTORIA—The Astoria Pulp & Paper Co. will build a paper mill on 11th St. and Tayler Rd. Estimated cost, $250,000.

Pennsylvania

BLAIRSVILLE—S. S. Richard, Altoona, will build a hospital and group of institutional buildings near here, consisting of sewage dispesal plant, reservoir, administration building, etc. F. McCrooks, Jones Law Building, Pittsburgh, architect.

PHILADELPHIA—N. Drassner, 1909 South 6th St., will build a two-story, 48 x 116 ft. chemical factory at 612-616 Moore St. Estimated cost, $20,000. H. H. Kline, 536 Mifflin St., engineer.

South Dakota

ABERDEEN—Dr. R. L. Mudry will receive bids until March 18 for the construction of a chemical building here. J. W. Henry, architect.

Texas

NORTH FORT WORTH—The Bureau of Yards & Docks, Navy Department, Washington, D. C., will receive bids until March 10 for the construction of an argon production plant here, to consist of an office and laboratory building, lime storage shed, compression building, separation building, pressure reducer house, nitregen cylinder house, carbon dioxide removal system and lime mixing shed. Estimated cost, $607,250

FORT WORTH—The Evans Thwing Refining Co. has awarded the contract for the construction of an oil refinery, to the Reeves Bros., Alliance. Noted Dec. 30.

McKINNEY—The Texas Cotton Mills Co. will build an indigo-dye plant. Estimated cost, $60,000.

SAN ANGELO—The city will install a filtration plant. Estimated cost, $30,000. R. H. Henderson, mayor.

YOAKUM—The Texas Hide & Leather Co., recently organized, will build a factory for the manufacture of coarse grades of leather. A. Hofheinz, manager.

Virginia

ORANGE—The West Virginia Timber Co., 510 Charleston National Bank Building, Charleston, W. Va., will build an acid and byproducts plant and saw mill here. Estimated cost, $500,000. G. E. Breece, president.

ROANOKE—The United States Potash & Brick Corp., recently incorporated with $1,000,000 capital, will build a plant to have a daily capacity of 25 tons of caustic potash. O. T. Dennhardt, Box 956, manager.

Washington

TURNER—The Loon Lake Copper Mining Co., 408 Columbia Bldg., Spokane, will build a concentrating mill to have a daily capacity of 100 tons. J. McCormick, president.

West Virginia

CLARKSBURG — The Clarksburg Water Board will build a one-story, 20 x 25 ft. filtration plant and install filter equipment and piping.

Alberta

EDMONTON—The City Council will build an addition to the filtration plant. Estimated cost, $30,000. C. E. K. Fox, clk.

British Columbia

KIMBERLY—The Consolidated Mining & Smelting Co. will build extensive additions and improvements to the concentration plant to treat the increased tonnage of the Sullivan mine here.

PORT MOODY—The Moody Rolling Mills, Ltd., Pacific Building, Vancouver, will build a steel rolling mill here.

VANCOUVER — The Bowena Copper Mines, Ltd., 419 Rogers Bldg., will build a concentrating mill. C. M. Oliver, secretary.

VICTORIA — The Tudhope Electric Metals, Ltd., will build a smelting plant. Estimated cost, $8700.

Ontario

CONISTON—The Mond Nickel Co. will establish three new furnaces, thereby doubling the capacity of its plant. C. V. Corliss, manager.

HAMILTON—The Dominion Foundries & Steel Co., Ltd., is receiving bids for the construction of a new plate mill having a capacity of 12,000 tons per month. Noted Feb. 1.

NORWAY—The city will build a sewage disposal plant. Address J. Brown.

OTTAWA—The Board of Control will soon award the contract for furnishing 30,000 lb. of liquid chlorine. A. F. MacCallum, engineer.

OTTAWA—The Canadian Government will establish a Central Resources Institute at an initial cost of $600,000 for buildings and laboratory equipment. The general idea is that the institute should combine the functions of the Bureau of Standards at Washington, D. C., also the duties of the Mellon Institute at Pittsburgh, Penn.

PORT ARTHUR J. J. Carrick, 13 Cumberland St., N., will build a pulp and paper plant. Estimated cost, $7,500,000. H. S. Ferguson, 200 5th Ave., New York City, engineer, preparing plans.

Quebec

MONTREAL—The Commissioners of the schools of Coteau and St. Pierre are in the market for equipment for their new chemical laboratory, manual training and art departments. D. I. Spence, 246 Beaver Hall, architect.

QUEBEC—Price Bros. Co., Ltd., 56 St. Peter St., will build a new pulp mill. Estimated cost, $1,000,000.

QUEBEC—The Valcartier Lumber & Pulp Co., Ltd., will receive bids in March for the construction of a pulp mill. Estimated cost, $350,000.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold a meeting in Buffalo, April 7 to 11.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its annual meeting in New York City from April 3 to 5.

THE CANADIAN MINING INSTITUTE will hold its twenty-first annual meeting on March 5 to 7, 1919.

THE NATIONAL FOREIGN TRADE COUNCIL will hold its sixth National Foreign Trade Council at the Congress Hotel, Chicago, Ill., on Thursday, Friday and Saturday, April 24, 25 and 26, 1919.

THE SOCIETY OF INDUSTRIAL ENGINEERS plans a national conference at New York March 18-21 at the Hotel McAlpin, at which there will be a discussion of labor by both employers and labor leaders. Internal plant organization and also the elimination of fatigue will be other leading topics.

Industrial Notes

THE ALL-RUSSIAN CENTRAL UNION OF COOPERATIVE SOCIETIES invites American manufacturers and producers to send price lists and catalogs in duplicate to the headquarters of the Union, Liebes Building, 167 Post St., San Francisco, Calif. It is stated that the All-Russian Central Union represents the bulk of Russia's buying power.

THE WELLMAN-SEAVER-MORGAN CO., Cleveland, Ohio, held its annual meeting of stockholders on Feb. 18 and re-elected the retiring board of directors as follows: Edwin S. Church, F. E. Borton, W. H. Cowell, F. B. Richards, S. T. Wellman, E. H. Whitlock of Cleveland, S. H. Pitkin, Francis Seiberting and F. A. Seiberling of Akron, O. The directors have elected the following officers: Edwin S. Church, president and general manager; S. H. Pitkin, vice-president; Geo. W. Burrell, second vice-president; and W. H. Cowell, secretary and treasurer. Mr. G. W. Burrell, who was elected second vice-president, has been in the continuous employ of the company for twenty-one years. He will have entire charge of the company's works both at Cleveland and Akron.

For the purpose of aiding American manufacturers in expanding export trade to the twelve nations of Central Europe and Asia Minor which recently declared their independence and formed an alliance known as the Mid-European Union, and to expedite the delivery to these countries of such materials as is needed by them, a bureau of information and education has been created with offices in the Union headquarters, McLachlen Building, 10th and G Streets, N. W., Washington, D. C. The countries which have pledged themselves to the Union of Independence through official representatives in this country are: Czecho-Slovaks, Poles, Jugoslavs, Ukrainians, Uhros-Rusins, Lithuanians, Rumanians and Italian Irredentists. Unredeemed Greeks, Albanians, Zionists and Armenians. The following are the representatives in this country: T. G. Masaryk, (for the Czecho-Slovaks), T. M. Helinski, (for the Poles), Dr. Hinko Hinkovic (for the Jugoslavs), Nicholas Ceglinsky (for the Ukrainians), Gregory Ignatius Zsatkovich (for the Uhro-Rusins), Thomas Norus Narusevicius (for the Lithuanians), Capt. Vasile Stoica (for the Rumanians), Charles J. Tomazolli (for the Italian Irredentists), Christos Vassilakaki (for the Unredeemed Greeks), Christo A. Dako (for the Albanians), Itzamar Ben-Avi of Jerusalem (for the Zionists), G. Pasdermadjian (for the Armenians). The bureau announces that the Central European countries are in immediate need of materials and commodities of every description and it is the intention to gather all available information valuable to the manufacturers of this country with as to the character of goods desired and as to specifications. In other words, the bureau will act in an advisory capacity to both the purchaser and seller. Mr. J. Nichols is assisting in directing the affairs of the bureau.

Manufacturers' Catalogs

THE MILWAUKEE RELIANCE BOILER WORKS, Milwaukee, Wis., calls attention to Bull. No. 101, on Sharp-Bassett gas producers. This booklet describes and illustrates combined steam and gas generators, improved gas producer, gives a curve showing the full consumption of a modern producer gas engine at various loads, comparative costs of power of various types of engines and producer gas for power and fuel.

THE SHAWINIGAN ELECTRIC-METALS CO., Ltd., Montreal, Canada, has issued an attractive booklet, No. 2, dated Dec. 2, 1918, entitled "Shawinigan Magnesium," which contains 36 pages on foundry practice in using magnesium, physical properties, chemical properties, chemical uses, alloys, table of comparative costs, commercial forms, packing and quality.

THE WESTINGHOUSE ELECTRIC & MFG. CO. and associated companies have issued the annual catalog of electrical supplies containing a list of all apparatus manufactured by the company or obtainable through its district offices and agent-jobbers. The catalog, comprising 1264 pages, contains a complete cross index and supply number index.

THE SCIENTIFIC MATERIALS CO., Pittsburgh, Pa., has just issued a "Blue Book" of scientific laboratory equipment. The distinguishing feature of this catalog is that not a single item listed is "Made in Germany." This is noteworthy when it is considered that the catalog comprises over 650 pages and contains a complete list of apparatus, equipment and chemicals.

THE DEISTER CONCENTRATOR CO., Fort Wayne, Ind.: Bull. No. 3 illustrates and describes in 24 pages Deister-Overstrom Diagonal Deck Concentrating Tables.

THE GREEN FUEL ECONOMIZER CO., Beacon, N. Y., has just received an attractive booklet from the press, Bulletin 151, on "Green's Economizers." This 64-page booklet deals with the first economizer, heat of fuel present in flue gases, economizer practice, secondary advantages, special uses, photographs of installations, steam tables and dimensions.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., East Pittsburgh, Pa.: Catalog 33, entitled Westinghouse Alternating-Current Motors, describes and illustrates in 80 pages classification and selection of a-c motors, squirrel-cage induction motors, headstock motor equipments for woodworking lathes, wound-rotor induction motors, elevator motors, type AR, single-phase, constant speed motors and also synchronous motors.

HAMILTON & HANSELL, INC., New York, has issued a booklet on the Rennerfelt electric arc furnace which illustrates and describes this furnace.

Speaking of Propaganda

ACCORDING to a time-honored custom, the dancers usually defray the expense of the orchestra. So Germany, having indulged in a wild orgy and frightful revelry for four years, is about to be presented with the bill; and signs are not lacking that she is looking furtively about for a side exit through which she may escape the collector. The whining press dispatches emanating from her political leaders urging justice and leniency on the part of the Allies, and even threatening dire consequences if the Peace Conference lays on too heavy an indemnity, are but palpable attempts to secure sympathy from thoughtless minds.

German propaganda is still in our midst—deceptive, insidious, baneful. It rears its head on the front page of the daily press, in whispered talk on the street and in published interviews with prominent personages. It is the most effective weapon left in the hands of an unchastened and unrepentant nation, and it can yet work untold harm unless intelligent people steel their hearts against it. In many respects it is unfortunate that Germany was not whipped into decisive military defeat, because that outcome might have chastened her pride and brought home a lively sense of the enormity of her crimes. Perhaps this desirable end may yet be accomplished when her people realize that the bill must be paid and that it is huge beyond the dreams of the indemnities which her own rulers had planned to exact from the Allies. No qualms of conscience or false spirit of magnanimity should deter those who are charged with fixing the terms of peace from exacting the last full measure of just reparation from Germany. Her land is unscarred by shot and shell; her factories and machinery are intact; her people have homes and will get food enough for subsistence; she has natural resources such as potash that can be administered in the interest of the Allies; her people are sufficiently accustomed to heavy taxation to warrant continuance of that means of securing national funds. In short, Germany is able to pay, and no amount of propaganda should swerve the Allies from the only course that will satisfy the great mass of their peoples.

The Blight of Blatherskite Rule

EVERY issue of *Science* contains memoranda of the shift, by leading men, from the faculties of colleges and universities over to industry. Of the change from industrial work to the high estate of professorship there are very few notes. In the Employment Bureau

of the Chemists' Club there are constantly increasing applications for positions as chemists, but only a few applicants are even willing to teach, far less desirous of so doing. The exodus from teaching seems to be more particularly from the so-called freshwater institutions: the State colleges and the universities of interior States.

Now, teaching is the greatest of the arts, and while its emoluments are seldom high, many such posts offer opportunities for research, and also for consultation. Despite the incursions of dancing masters and sleight-of-hand performers, there still inheres a great dignity to the title of professor. What is the trouble, then? We answer, frankly, politics. Trustees are appointed who are without scholarship or educational ideals. They do not even know enough to keep their hands off what they do not understand. Sometimes a strong administrator in the person of the president can prevent them from meddling, but often again the trustees are too ignorant to forbear. They make life impossible for a conscientious educator.

The ideals of the majority of our State colleges and universities are splendid. The student bodies are no less than inspiring. They are eager to learn, and they lack the extra-academic "activities" which beset many of the Eastern institutions to the inhibition of serious study. The whole organization would be most promising, if it were not for a succession of dunderhead trustees appointed by the vagrant fancy of a series of transient Governors.

What these institutions lack is democracy at the top. Democracy implies working together, which is something the political trustees cannot understand. They strut about in their comedy authority, and insult professors and instructors; they make foolish demands, and they connive to replace useful and gifted teachers with their own relatives and friends. They interfere with discipline in the interest of grocers and haberdashers. A goodly number of them are infernal nuisances, for it is within the power of a single trustee to destroy the morale of a great institution.

We are disposed to favor a civil service commission to pass on all nominees for the trusteeship of colleges and universities that receive Federal aid, with the power to remove those who prove incompetent. The need for good instructors is pressing, very pressing, and many of the best are leaving their posts because of unendurable conditions, brought about by blatherskite rule!

Metallurgy and Civilization

SAVANTS have pictured primitive man a beast of the jungle mouthing almost meaningless gibberings. Fortunately he discovered fire, and with this knowledge migrated into more temperate zones, where later with his new-found friends, a bow and arrow, he became hunter instead of hunted. Perhaps in this dim, uncertain eon the savage picked up yellow gold and white tin in the stream beds by which he penetrated the pathless forests, or found red copper in the ashes of a fire fortunately builded under boulders of ore. And in some way one found that white and red metal would melt together to form a different thing we now call bronze. When the savage learned that this new metal could be made into superior tools and weapons he was a savage no longer.

Long millenniums of barbarism then passed, during which ancient man progressed mightily by virtue of his inherited wisdom. The making and the use of pottery in cooking reacted powerfully on his development; he changed from hunter to herdsman or farmer by the domestication of animals and the invention of irrigation. Yet the bronze age passed after ages of groping metallurgy, when the ancient smith produced steel in his primitive forge and discovered how to harden it after being cunningly wrought. Metallurgy had again opened the gates of civilization!

All this happened long before the invention of writing, and is known to us only by the remaining fragmentary handicraft of the ancient artisan. Recorded ideas now enabled man's culture to advance with increasing speed to but yesterday, when gunpowder and the printing press leveled society, physically and mentally. Perhaps the last great step toward the latest civilization has just been taken by Watt and his steam engine. But meager indeed would be our comforts had not the modern metallurgist responded to the need of huge quantities of cheap steel for bridges and ships, rails and boilers, of strong metals for axles and engines, of special alloys for electrical and domestic uses.

The word metallurgy images to many minds a small, dark, smoky, smelly iron foundry, or to others a high board fence surrounding furnaces glaring with white heat, and powerful machinery superhuman in power and dexterity. But in its entirety modern metallurgy influences our civilization down even to the commonest tools of life, and the initiated wonders to what state of savagery we would drop should it become a lost art.

German Chemical Patents Take On New Aspects

THE Chemical Foundation, Inc., has recently been formed to take over the 4500 German chemical patents at present owned by enemy aliens. The charter of the corporation is so framed that under the patents non-exclusive licenses only can be granted on equal terms to all proper applicants and must be granted to the United States free of cost. By Executive order obtained under the provisions of the Act of Nov. 4, A. Mitchell Palmer, Alien Property Custodian, has sold to this company for the sum of $250,000 all the German chemical patents which have been taken out in the United States.

It is well known that the German patents were not taken out to obtain exclusive manufacturing rights in this country, but to maintain exclusive sales. The sales departments of the various German companies feared Swiss, French and English competition and prevailed upon their manufacturing department to allow it to work out patent descriptions of processes which would protect their features but not disclose their actual methods of manufacture. As a matter of fact, the methods usually described were chosen for their excellently small yields. A mere sample of the product was all that was needed to fill the patent requirements and satisfy the sales department by furnishing it with a weapon to strike down competition.

Such an end to the mass of faked, camouflaged, false patents is as glorious as the victory in Europe. However,

the final success of the venture will require addition to the board of directors of men as eminent in the field of industrial science as the present members are in legal, executive and financial circles. The Chemical Foundation, Inc., will not be a commercial success unless it can supply manufacturing yield methods as well as patents. It cannot fail in doing some good in that it will prevent foreign competition on the commodities covered by its patents. Not having been formed for financial profit, vast sums of money will be collected and expended. Co-operation will be obtained to an extent not hitherto conceived, but men with a scientific insight should be in the pilot house as well as below the deck.

Sulphur Patents Are Decreed Invalid

THE United States Circuit Court, sitting at Philadelphia, has dismissed the infringement suit of the Union Sulphur Co. vs. the Freeport-Texas Co. with the verdict that the patents lacked inventive substance.

Too many patents of doubtful validity are being issued which may or may not be of sufficient financial value to merit such a costly legal battle as has just been closed with the Frasch sulphur patents. While we are cleaning up the German patent system, can we not extend the good work and establish patent limits?

Deflating Prices Mobilizing Industry

THROUGH the proposals of Secretary of Commerce Redfield war-time prices are to be deflated and industry is to be mobilized for normal peace-time activity. The principle of *laissez faire* is not to be allowed to obtain in the commodity markets. It is pointed out on behalf of the Industrial Board of the Department of Commerce, formed under Secretary Redfield's plan, with George N. Peek as chairman, that the law of supply and demand cannot be expected to cure what it did not create.

The condition of war-time control of prices, set at a high level in order to stimulate production, is not the only instance of the law of supply and demand not operating. It is a facile assumption that when prices are under control by pools or agreements among sellers, things interdicted by the Sherman law, the law of supply and demand is altogether suppressed, while when such agreements are suppressed the law of supply and demand operates. No more egregious blunder could be made. Time after time the iron and steel industry has given the plainest testimony that such is not the case. Repeatedly after a period of heavy buying and advancing prices it has, without agreement, held to existing prices neither because of agreement nor because of demand balancing supply, but merely and solely because the individual producers all recognized that to cut prices would be to precipitate a great decline, demand being too light to establish a price level only slightly lower than the existing one, and being certain, moreover, to be diminished rather than increased by price reductions. The mills had unfilled obligations with customers, and a break in the market would kill more of that tonnage than it would produce new tonnage. There was less to gain than to lose.

By and by the time arrived when the steel mills observed that there was more to gain than to lose by giving prices a free rein. Bottom was then reached and the market eventually recovered, a new "buying movement" being inaugurated. Thus the endless cycle has been followed. If steel were not used for construction or "investment" purposes, if jobbers and manufacturing consumers pursued a rule of maintaining the same stocks at all times, and if mill deliveries against orders were made with the same degree of promptness at all times, prices of steel might fluctuate quite closely in accordance with the supply available and the actual consumptive demand. As it has been, the expressed demand exceeded at one time the actual consumptive demand and at other times fell short of it. Construction jobs were undertaken partly in a speculative spirit, being proceeded with not solely because the facility was needed at the particular time, neither sooner nor later, but because the buyer did not wish to overstay a rising market. Let us be thankful, therefore, that at last circumstances so clear and compelling have arisen as to force the admission that the law of supply and demand does not always set prices when the conspiracies in restraint of trade, interdicted by the Sherman law, do not exist.

There is no doubt that Secretary Redfield's Industrial Board will be able to accomplish some very good results. Judge Gary in his address to representatives of the iron and steel industry on March 6 referred to Mr. Redfield as "a very wise and thoughtful man," and Mr. Peek, chairman of the Industrial Board, who in turn addressed the meeting, impressed the manufacturers as being a man of true business instincts.

The board has two sources of power. In the first place, it can furnish assurance to a given industry that the co-operation of all industries will be sought for the purpose of securing the reduction in prices of building materials essential to the resumption of construction work. The brickmakers do not care to reduce prices if the steel producers do not, nor the steel producers if the cement makers do not, since for the full stimulation of construction work all items of cost should be reduced. Each industry, no doubt, would be willing to make its contribution if others would co-operate.

In the second place, the Industrial Board has the lever of Government or Government-controlled purchases. The Navy Department has considerable buying to do and some other Government departments have not a little, while there is a large volume of railroad buying that could be compassed if prices were made reasonably attractive.

To avoid possible disappointment, however, it should be recognized that the contemplated operation has its limitations. It cannot create an ideal condition on which years of industrial activity can be built. It does not know precisely how eager the investor will be to exchange "safe" investments, such as many bonds, for works of construction. It does not know precisely how hard workmen are going to be willing to work in future. It can develop a "recommended" price for merchant steel bars, perhaps even for screw stock and shafting, but must stop before it gets to farm implements, machine tools and automobiles. In particular, it seems to be the program to carry the activities, in establishing or re-establishing the law of supply and demand, only to the point of time when through decrease in the cost of living and other influences it will be fitting and proper that wages should decline. Wage declines, with fresh deflation of prices, will hardly be under Government auspices.

Readers' Views and Comments

Colloidal Condition of Silver Chloride

To the Editor of Chemical & Metallurgical Engineering

SIR:—Reading the editorial notes on Colloids in your issue of Oct. 15 made me recall an instance of what I suppose was a colloidal condition of silver chloride. This was encountered in laboratory control of the operation of a blast furnace that treated slag from reverberatory furnaces in which Lake copper concentrates were smelted.

In making determinations of the silver content of the impure copper ("cupola blocks") yielded by the blast furnace, it was noticed that at times the silver chloride, formed by adding HCl to the nitric solution of the copper, failed to settle out completely, even after one or more days of standing. Inspection of the records of such cases showed that they occurred uniformly whenever the blast furnace charge included, together with regular slag from the smelted concentrates, any considerable proportion of the slag that was formed from the reverberatory refining of "cupola blocks" themselves. I do not know whether any especial interest attaches to the foregoing, but offer it merely as an observation. R. F. WOOD.

Sandusky, Ohio.

The Analysis of Red Lead

To the Editor of Chemical & Metallurgical Engineering

Sir:—Soon after the publication of "Notes on the Analysis of Red Lead" in CHEMICAL & METALLURGICAL ENGINEERING, Jan. 1, 1919, my attention was called to "A Rapid Method for the Analysis of Red Lead and Orange Mineral" published in the *Journal of Industrial and Engineering Chemistry*, March, 1916. This is a hydrogen peroxide-potassium permanganate method and is said to be finding more and more favor with large users of red lead on account of its simplicity and accuracy.

As to its simplicity and easy adaptability to routine methods there is no question. However, I should simplify the details given in the paper referred to. There is no need of hot water or dilution and it is quite as simple to use a regular N/10 permanganate solution with a factor 0.03428 for the Pb_3O_4 as to use a computation based on an iron value of the permanganate.

As to the accuracy of the method, I have compared it on three samples of red lead with the iodide method, having standardized the permanganate with Bureau of Standards standard sodium oxalate and with ammonium ferrous sulphate. The sodium thiosulphate used in the iodide method was standardized with this permanganate. The samples were weighed with the same one-gram weight on the same balance and the titrations were made from the same section of a single burette at room temperatures not varying more than one degree during the analyses.

Sample I. By iodide, 92.55 and 92.55 per cent; by peroxide, 91.61, 91.32, 91.90, 91.63, 91.96 per cent. Average, 91.62 per cent.

Sample II. By iodide, 90.49 and 90.49 per cent; by peroxide, 89.95, 89.71, 89.71, 90.15, 90.50 per cent. Average, 90 per cent.

Sample III. By iodide, 87.07 and 87.07 per cent; by peroxide, 87.74, 87.07, 87.41, 87.38, 86.81 per cent. Average, 87.30 per cent.

In the peroxide method the permanganate was measured in a second burette and two burette readings are necessary, while in the iodide method only one burette reading is taken and represents the iodine actually freed by the red lead and not a left over portion of a measured in amount of reagent. This probably accounts for the variations in the numbers for the peroxide method.

On the whole I should say the checks were as close as could be expected and sustain the claim for simplicity and accuracy. W. F. EDWARDS.

Detroit, Michigan.

Economics in the Zinc Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—I hope that the discussion caused by your recent publications on zinc metallurgy may lead to tangible results, and not to the usual very general and non-committal statements. Unfortunately for the writer, as is doubtless the case with numerous others, the invitation to participate in such discussion should really come from the metallurgist's superiors, and will be lacking in most instances.

It has been my experience that the capital which is backing the zinc smelters will not permit very radical changes unless the chances for success are good, and therefore I believe that the near future will show only gradual improvements. The vertical retort with continuous charging is likely to be the first effort of our industry not only to improve the retorting practice now in vogue, but also to overcome the labor shortage on the one hand and the growing inefficiency of labor on the other.

Roasting of zinc ores will, in my opinion, continue and should most certainly be accompanied by the extraction of sulphuric acid. However, the roasting process itself is in almost greater need of radical improvement than is the smelting. There is really no entirely efficient and satisfactory roaster in existence today, especially for the flotation concentrates, which will presently be the only type of ore we are asked to smelt.

Briquetting of furnace charges has been tried again and again, but in spite of its obvious advantages has not been worked out to a definite success. The large amount of air which is invariably present with briquetted charges appears to be the greatest drawback in retorting, and we may have to use a combination of briquets and the usual fine retort charge to reduce the voids.

The greatest difficulty in the retorting of zinc ores is still the condensation of the metallic fumes, and practically no progress has been made in improving the existing condensers, or in designing a new type.

The often disagreeable working conditions, the presence of excessive heat and obnoxious fumes, and the great physical effort now required, must be overcome to make the future zinc smelter a place to which labor will be attracted. We will have to get away from the methods of producing zinc by the spoonful, and must develop apparatus which will yield the best metallurgical results possible, combined with the lowest amount of labor needed, and at the same time take the responsibility for the finer points in our art out of the hands of practically trained labor, and vest it in the metallurgist, as is customary in the smelting of iron and copper.

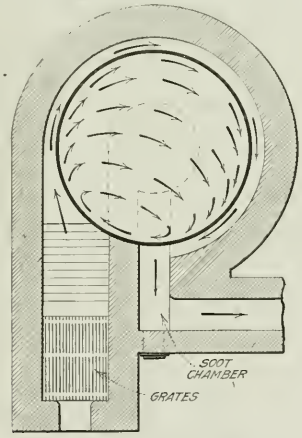
ZINC SMELTER.

Furnace Settings for Caustic Pots

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to my article, "Furnace Settings for Caustic Pots," which appeared in your Jan. 15 issue, please note that the words "counter-current economizer" in the caption under the title should have been omitted. As stated in the text on page 67, particularly in the claim quoted from my patent, the liquor in the pot is caused to rotate by means of the tangential application of the products of combustion to the exterior of the pot, the direction of travel being concurrent with the rotation of the liquor.

Also, you will note that the arrows, indicating the direction of the liquor rotation in the right-hand pot in Fig. 3, page 65, were inadvertently pointed in the wrong direction. This probably accounts for the use of the words "counter-current" referred to above.



CIRCULATION OF LIQUOR IN NICKLE TANGENTIAL DUTCH OVEN

My theory, as to why the natural rotative circulation of the liquor is concurrent rather than counter-current with the heating gases, is illustrated in Fig. 1. The heating surface adjacent to the combustion chamber is subjected to the most intense heat, whereas the reverse is true at the end of the circumferential travel of the heating gases or adjacent to the soot chamber.

Starting with a pot of cold liquor, the two temperature extremes being in close proximity, it is evident that convection or eddy currents will be set up in the liquor, the direction of which will be clockwise as indicated. Gradually the cold particles of liquor, remote from the high temperature heating surface, come within the influence of these eddy currents until the arcuated path of active circulation is established tangentially to the orbital heating surface, and in substantially a horizontal direction with reference to arcs struck about the axis of the pot, the rotation being in the direction of decreasing application of heat, or concurrent with the travel of the heating gases.

Novel Method for Treating Sulphur Ore

To the Editor of Chemical & Metallurgical Engineering

SIR:—The war stimulus to the sulphur mining industry resulted in the serious attempt to develop and operate numerous Western sulphur deposits, mostly of solfataric origin and not adapted to the application of the celebrated Frasch underground liquation process to the problem of the recovery of the native sulphur from the gangue with which it is associated. Heretofore the method in use in this country was the liquation process, using the principle of melting or liquefying the sulphur in a closed chamber or retort by means of superheated steam and the recovery of the sulphur by simple drainage methods. This apparatus in any of the forms used was expensive to operate and the recovery of the sulphur was very low, sometimes not more than 25 per cent; besides it was costly in operation and very uncertain as to results under the varying physical conditions of the material to be treated. Several mechanical adaptations of this method have been resorted to, but in general the process is a very imperfect one from the standards of cost and efficiency.

Attempts to recover the sulphur by flotation have been made in the laboratory and by means of experimental plants, and there is promise of very good results in this line. However, the problem has engaged the attention of a number of operators, with the result that some novel metallurgical ideas have been evolved, at least to the experimental stage. One of these is based on the familiar "shot-tower" idea. The sulphur with the gangue is submitted to treatment under pressure by superheated steam, with the result that the sulphur is liquated and drains through the perforated bottom of the retort along with more or less of the fine gangue and dirt, the separation of which from the liquid sulphur is one of the problems of other liquation applications. In falling a short distance, not more than 10 ft., the sulphur forms small spheres in a similar manner to the action of the streams of molten lead in the shot tower, and at the bottom of the chamber there is accumulated a mixture of these "shots" and the fine material. The sulphur "shots" are very pure and free from dirt and fine rock. Their further separation is an easy matter of screening and separation by methods familiar in other applications. This novel metallurgical idea is being tried out in an experimental way in Chicago, and patents have been applied for.

It is interesting to consider whether the idea might have application to any other metallurgical operations and whether its possibilities in the sulphur field are of importance.

Twenty-First Annual Meeting of the Canadian Mining Institute

Report of Business and Technical Sessions, With Special Reference to the Production of Such War Minerals as Manganese, Platinum, Chromite and Molybdenite—National Research and International Co-operation—D. H. McDougall Elected President

THE Canadian Mining Institute celebrated the attainment of its majority at the annual meeting held in Montreal, March 5-7, 1919. In his opening address President D. B. DOWLING referred to the cordial and friendly relations existing between the Canadian and American mining engineers, as evidenced by the exchange of visits at the annual meetings of the respective societies. This practice has been growing in recent years and should become an established custom. It was again referred to by MR. H. V. WINCHELL, president of the A. I. M. E., who spoke on the subject of international co-operation in mining, and who advocated intermingling of Canadian and American mining engineers as an effective measure for making imaginary boundary lines non-existent except for political purposes.

President DOWLING reviewed the assets of Canada and said that her economic aim should be to develop her natural resources and thereby improve her local markets. Canada's products should be offered to the world in manufactured form whenever possible; and he placed on mining engineers the responsibility of developing in the highest degree the mineral resources of the Dominion.

CHANGE OF NAME PROPOSED

At the annual business meeting the Institute became involved in a long discussion over DR. STANSFIELD'S resolution to change the name from Canadian Mining Institute to Canadian Institute of Mining and Metallurgy. Difference of opinion centered mainly in the function of the Institute—whether it was devoted to the general industry of mining without regard to the different phases, such as mining, metallurgy, geology and chemistry, or whether it was a professional body concerned with the technology of methods and processes. Discussion seemed to favor the former view, *i.e.*, that the Institute is devoted to the mining industry as a whole and is not primarily a technical organization. DR. STANSFIELD'S resolution was disposed of by referring it to the membership at large for letter ballot.

Certain amendments to the by-laws were proposed and referred to the membership. One related to classification of membership, introducing the grade of "professional member"; and the other was concerned with the election of officers and council. The purpose of establishing "professional members" was the convenience of council in dealing with other engineering bodies in Canada on subjects involving the professional status of mining engineers. The object of the amendment relating to officers and council was to provide machinery whereby the Institute would be in closer touch with the interests of the provinces. It calls for an increase in the number of vice-presidents from four to six; the redistricting of the Dominion into six districts which shall have direct and equal representation on council.

The question of the salaries received by technical employees in the civil service of the dominion and provincial governments was discussed at some length, and finally the Institute passed a resolution urging the Government to provide larger salaries for its officials and employees whose duties call for technical training.

MR. D. H. MCDOUGALL, president of the Nova Scotia Steel & Coal Co., was elected president of the Institute for the ensuing year.

SYMPOSIUM ON MOLYBDENUM AND CHROMIUM

Several papers were scheduled dealing with the mining, concentration and metallurgy of molybdenum and chromium ores. MR. B. C. LAMBLE described the manufacture of ferromolybdenum at Orillia, by smelting in the electric furnace a mixture of green or raw concentrates of molybdenite with lime and carbon. Eighty per cent of the molybdenum fed to the furnace was recovered. Volatilization losses were very low, but there was a dust loss of 11 per cent and a slag loss of 7 per cent. Ninety per cent of the metal in the latter, however, was recovered by table concentration.

Recent progress in the concentration of molybdenite was discussed by MR. H. H. CLAUDET. He cited Elmore's successful pioneer work in concentrating molybdenite by flotation more than thirteen years ago, and he reviewed the later work of Wood in developing the film-flotation machine and process which had been so successful in producing molybdenum concentrates during the war. Still a later development was the application of the Callow cells with the adjunct of a screen to separate the flocculent molybdenite from the granular silica pyrite. In a flow-sheet which he exhibited the ground ore was first floated in a rougher cell which yielded a finished tailing and a dirty concentrate, the latter being cleaned in a second cell. The second tailing was returned to the rougher cell because it was quite rich in molybdenite. The concentrate contained some pyrite and silica, and these were separated by passing the concentrate over a Callow traveling-belt screen. The molybdenite formed flocks which remained on the screen and were readily separated from the impurities which passed through. This latter product was returned to the rougher cell on account of its high molybdenum content, and ultimately the silica and pyrite would go out with the cell tailing, while the molybdenite would flocculate and be caught on the screen. This method effected a 95 per cent recovery in a concentrate containing 90 per cent MoS_2. The utility of screening

was shown in raising the grade of a 3 per cent MoS_2 flotation concentrate to 65 per cent, and one of 12 per cent to 76. In discussion it was brought out that soluble sulphates interfered with the process, as also did chalcopyrite. Mica was not objectionable unless present in large amounts. Oxidized ores of molybdenum did not yield well.

New occurrences of chromite in Canada were described by DR. ROBERT HARVIE in an illustrated lecture; and the concentration of chromite was the subject of a paper by MR. L. K. FLETCHER. Discussion elucidated the fact that Canadian chromite could be produced and sold at a profit for $1 per unit in 50 per cent concentrate, as against the quoted price of $1.75 per unit for the New Caledonian product. It would be essential, however, to have at least $1 per unit for the domestic product in order to provide insurance against the irregular ore-bodies.

War-Time Search for Platinum and Manganese

The lengths to which Canada went in an effort to secure adequate supplies of needed war minerals were well shown in an illustrated lecture by MR. G. C. MACKENZIE. He described his explorations on the Saskatchewan River and on the Tulameen in British Columbia, where large areas were prospected with hand augurs and with Empire and Keystone drills. Work on the Tulameen yielded results of 35c. per cu.yd. in gold and platinum, and was considered encouraging; but winter set in before drilling could be carried further, and the war ended before the winter was over. The area is still regarded as worth investigation by private concerns.

Manganese was sought on the Island of Vancouver and some deposits were found carrying from 30 to 50 per cent. The matter of making ferromanganese on the Canadian Pacific coast was investigated, and it was finally determined to be commercially impracticable on account of the cost of power. With ferromanganese selling at $100 per ton in the Eastern metallurgical centers, and Western power costing 7 mills per kw.-hr., the scheme would not be feasible. Power at 2 mills would be necessary for success. Canada used 1000 tons of ferromanganese monthly during the war, and had to import all of it from the United States or Great Britain.

International Co-operation in the Mining Industry

One day of the session was designated as American Institute Day, and was devoted to joint discussions relating to industrial relations, principles of taxation, co-operation among small concerns in the same district, etc. MR. H. C. PARMELEE outlined the changes that have been and are occurring in the relations between employer and employee, citing the most advanced customs among the leaders of industry in Europe and the United States. The subject of taxation was presented by MR. THOMAS W. GIBSON. SIR JOHN WILLISON spoke in advocacy of Government aid to the mining industry just as it is given to the agricultural or fishing industries. He approved the bounty for metal production and urged the participation of the Government in the development of the country through national industrial and scientific research. He thought that technical societies should address themselves to the education of legislators in regard to research, and hold sessions at the capital while Parliament is in session so that members might attend some of the meetings. Special programs for the information of legislators would be an effective method of education.

The Problem of National Research

DR. A. P. MACALLUM of the National Advisory Research Council addressed the Institute on the functions of the Council, which are as follows: (a) The investigation of standards of weight, measure, volume, etc.; (b) standardization of technical and scientific apparatus; (c) standardization of raw materials and products of Canada used in the arts and industries; (d) improvement of technical processes; (e) research to promote the utilization of the natural resources of Canada; and (f) the encouragement of trade research associations, to be assisted by the Government with free quarters and expert advice. He regarded the last as the most important function of the Council because through the development of Canada's potential industries she would be enabled to meet her future debts, pensions, etc. His remarks were the subject of an adjourned meeting at which the policies and proposals of the Research Council were warmly discussed and finally made the subject of a resolution in which the C. M. I. council was directed to investigate the proposals of the Advisory Council of Scientific and Industrial Research and determine the advisability of the proposed procedure.

Applying Powdered Coal in Blast Furnaces

A paper of unusual metallurgical interest was that of MR. W. L. WOTHERSPOON on the use of pulverized fuel in smelting copper-nickel ores in the blast furnaces. He reviewed the experiments started by the Tennessee Copper Co. and later by the International Nickel Co. The conditions at the two plants are essentially different, because the former has a charge consisting mainly of lump ore, while the latter uses 75 per cent of roasted ore that gives a screen analysis showing 53 per cent on 1½ in., 16 per cent on 1 in., and 31 per cent through 1 in. Tests now under way have been going on for more than two months and considerable economies in fuel consumption have been effected. The powdered coal is blown into the furnace through the tuyeres, the same grade of coal being used as for reverberatory firing. Plans are under way to apply the method to lead smelting. Mr. Wotherspoon's paper will be published in the *Transactions* of the C. M. I.

MR. E. J. CARLYLE described some special equipment that had been devised for a copper smelter in Russia. It consisted mainly in four-compartment charge cars, ore bins and smelting furnaces, designed to save time and labor as well as distribute the charge effective in the furnace. A feature of the furnace was a water-cooled cast blister-copper spout which was found necessary in order to resist the action of a very corrosive matte.

MR. W. FLEET ROBERTSON gave the results of an investigation of a hoisting cable which had failed in very light service. It was found that the exterior of the rope was sound and appeared to be in good condition, while at the same time spots in the interior were

badly corroded, thus weakening the rope. A method of electrical testing was devised, depending on measurement of the resistance of the rope every three or four feet. This was found effective in locating corroded spots. As a preventive against this corrosion it was recommended that periodically the rope be immersed in hot liquid grease, as the ordinary surface greasing was insufficient.

The meeting was marked by a number of social features, including a smoker and the annual banquet. At the former there was an exhibition of films showing Canadian forces in action in the Great War, as well as an illustrated lecture on General Allenby's campaign in Palestine, by DR. H. M. AMI. Two lectures on military tunneling and mining were given by MAJOR R. W. COULTHARD and CAPT. L. B. REYNOLDS. At the annual dinner the principal speech was made by the DUKE of DEVONSHIRE, Governor-General of Canada. He lent official support to the project for industrial research and to Government aid for the mining industry. Not the least important of his remarks related to the unity of interest of the employer and the employee, and the necessity for generous and broad-minded treatment of our industrial problems. In this connection he saw a large duty devolving upon engineers.

Report of Alien Property Custodian on the Chemical Industry

THE activities of the alien property custodian have been too extensive ever to be fully reported, but interesting reading is to be found in the voluminous report filed this week. Three of the Big Six German dye companies, Bayer, Berlin and Kalle, did not give Mr. Palmer much trouble, but the Badische, Hoechst and Cassella proved to be quite elusive. These latter concerns were nominally owned by Messrs. Kuttroff and Pickhardt; Herman A. Metz; and Matheson and Shaw; however, an actual German ownership existed in each case. The Cassella Company U. S. patent assignments were recorded, but the fact that Messrs. Matheson and Shaw immediately reassigned them to the parent German concern was a secret. As the National Aniline & Chemical Co. was dependent on these patents, the title to which was supposedly transferred to it by the recorded owners, it can be seen how interested the Germans might have continued to be in the new American Co. The Metz transfer will prove equally illuminating and we quote verbatim from Mr. Palmer's report:

THE HOECHST COMPANY

The American branch of the great Hoechst Co. had for many years been conducted by Mr. Herman A. Metz. Prior to 1912, the New York corporation was known as H. A. Metz (Inc.), and a majority of its stock was always owned by the parent house. In that year the German company took over all but 10 shares of the minority stock which had previously stood in the name of Mr. Metz, leaving him the record owner of these 10, the only shares not held by them. At the same time the name of the New York corporation was changed to Farbwerke-Hoechst, so that the value of the good will might be firmly fixed in the German name. At about this time the anti-trust proceedings above referred to were commenced against these companies also. Mr. Metz settled for $40,000 the suit commenced against his company, and proceeded to make strong representations to the German house to the effect that the stock ought to be owned by him so that it could no longer be asserted that the German house was no longer doing business in America. A prolonged negotiation ensued, the Germans being very reluctant to make any change. At last in the summer of 1913 it was arranged that the 1990 shares held by the German concern should be transferred on the books to Mr. Metz; that in return he should execute a demand promissory note without interest for the sum of $597,000; that the note should be delivered to the German company, and the stock, together with a suitable transfer properly executed, should be deposited to the sole order of the German concern in a Montreal bank, as security for the note.

HOW PROFITS WERE DIVIDED

At this time and for many years previous the American company had been operating under a contract by which the German house appointed it its sole American sales agent and agreed to furnish it with goods, in return for which the profits were to be divided according to an arbitrary scale, irrespective of stock ownership. Under this arrangement the Germans were to have one-half the profits of the color business and 75 per cent of the profits of the pharmaceutical business, which, owing to the development of salvarsan and novocaine, had become of great importance. In return, and as a check on possible overcharges by the German house, Mr. Metz was to receive a percentage of their profits on the sales to the American company. An irrevocable power of attorney was given to Mr. Metz to vote the stock owned by the German company in the New York house and an option was reserved to the German company to purchase the stock in the event of Mr. Metz's death or retirement.

PROFITS SENT TO GERMANY AS LONG AS MONEY COULD BE REMITTED

This contract was continued unaltered after the stock transaction of 1913, and under it the profits were divided as long as it was possible to remit moneys to Germany. There was also an oral understanding between the parties that the note should not be payable except out of the stock or its proceeds, and that it could not be demanded as long as Mr. Metz should remain president of the company. It will thus be seen that the whole stock dealing produced no change whatever upon the rights of the parties. After it, as before, the share in the profits of each party remained the same; power to secure and pass title to the certificates remained as before in the hands of the German company alone; the voting power remained as before in Mr. Metz's hands; in fact none of the incident of ownership was in any way affected by the transaction.

At the outset Mr. Metz filed reports stating the existence of the note and the fact that certain stock was deposited as security for the same, but it was not until the ascertainment of the entire history of the transaction that the proof could be obtained that the transfer was not and was not intended to be of any effect. At last, however, the investigation thoroughly demonstrated this, and the stock has accordingly been taken over by me.

The Roessler & Hasslacher Chemical Co. people were equally unsuccessful in making a camouflaged American ownership title through the lawyer Oscar R. Seitz.

PHARMACEUTICAL HOUSE OF E. MERCK

Another portion of the report says:

In pharmaceuticals, the most important concern in the world was that of E. Merck, of Darmstadt. This was represented in this country by Merck & Co., a New York corporation which had an enormous and very profitable business in all kinds of medicinal preparations. The stock of this company appeared on the books to be owned exclusively by George Merck, a member of the family which owns the house of E. Merck, of Darmstadt. Investigation, however, showed that the profits of this company had always been remitted to the German house in a manner utterly inconsistent with the apparent stock ownership, and it now stands admitted that the stock was paid for with money of the German house and belongs to the latter. Mr. George Merck insists that he is the real owner of one-fifth of this stock by virtue of the fact that he owns 20 per cent interest in E. Merck, of Darmstadt. I am of the opinion, however, that indirect ownership of this kind cannot be recognized under the trading with the enemy act, and I have therefore determined that the whole of this stock is enemy owned and it has accordingly been taken over.

As there has been 35,400 properties taken over, the estimated value of which is $700,000,000, no attempt will be made to catalogue them. Next in importance and interest will be the action taken with the German owned patents.

CHEMICAL FOUNDATION, INC.

Mr. Palmer explains the German patent transaction as follows:

The idea was accordingly conceived that if the German chemical patents could be placed in the hands of any American institution strong enough to protect them, a real obstacle might be opposed to German importation after the war, and at the same time the American industry might be freed from the prohibition enforced by the patents against the manufacture of the most valuable dyestuffs. Accordingly, these considerations were laid before various associations of chemical manufacturers, notably the Dye Institute and the American Manufacturing Chemists' Association. The suggestion was met with an instantaneous and enthusiastic approval, and as a result a corporation has been organized to be known as the Chemical Foundation (Inc.) in which practically every important American manufacturer will be a stockholder, the purpose of which is to acquire by purchase these German patents and to hold them as a trustee for American industry, "for the Americanization of such institutions as may be affected thereby, for the exclusion or elimination of alien interests hostile or detrimental to the said industries and for the advancement of chemical and allied science and industry in the United States."

STOCK IN A VOTING TRUST

The voting stock is to be placed in a voting trust of which the trustees are to be the five gentlemen who for months have been acting as the sales committee which passes upon sales made by my department, that is to say, George L. Ingraham (former presiding justice of the appellate division, first department, New York Supreme Court); Otto T. Bannard (president, New York Trust Co.); Cleveland H. Dodge; Benjamin H. Griswold (senior partner of Brown Bros., bankers, Philadelphia); Ralph Stone (president, Detroit Trust Co.), and the charter is so framed that under the patents non-exclusive licenses only can be granted on equal terms to all proper applicants, and must be granted to the United States free of cost.

The company is capitalized at $500,000, of which $400,000 is to be 6 per cent cumulative preferred stock and $100,000 common stock, also limited to 6 per cent dividends. The first president of the Chemical Foundation (Inc.) will be Francis P. Garvan, of the New York bar, to whose clear vision and indefatigable industry I am chiefly indebted in the working out of this plan.

COMPANY HAS 4500 PATENTS

By Executive order obtained under the provisions of the act, I have sold to this company for the sum of $250,000 approximately 4500 patents; the remaining $250,000 has been provided for working capital so that the company may be able to commence immediately and prosecute with the utmost vigor infringement proceedings whenever the first German attempt shall hereafter be made to import into this country. The charter of the corporation provides that surplus income is to be used for the retirement of the preferred stock and thereafter for the advancement of chemical and allied science and industry.

The price thus paid was necessarily determined somewhat arbitrarily; the great majority of the patents were presumably valueless. The value of the remainder was entirely problematical and impossible to estimate. Substantially the entire industry having combined for the purpose of this purchase, it would have been impossible on public sale to find as a bidder any legitimate manufacturer. No other bidder could, therefore, have been found on public sale except some speculative individual who might have bought them for purposes practically amounting to commercial blackmail. The combination was not objectionable to public policy since it was so organized that any genuine American, whether a stockholder of the company or not, could secure the benefits of the patents on fair and equal terms.

Fate of the Water-Power Bill

The proposed water-power legislation which has been before Congress for the seven years of the present administration failed of passage when Congress expired March 4. After lengthy debate in committee and on the floor of both houses, conferees on the part of the House and the Senate agreed to report the bill favorably and it would undoubtedly have passed both houses if it could have been reached on the calendar. The proposed legislation did pass the House of Representatives a few days before the end of Congress by vote of 264 to 65, but failed to pass in the Senate, because it became entangled in the meshes of the filibuster which was conducted by Senators opposed to the President's policy in foreign affairs. Although there were informal assurances to Senators who had charge of the proposed legislation that there were at least 80 votes in favor of the measure in case it could be brought before the Senate, the bill did not obtain a hearing.

It will now be necessary for the advocates of water-power legislation to begin a campaign of education for the benefit of the new members of the House of Representatives and the new members of the Senate who are to take their seats in any proposed extra session of Congress which the President may call. Committee assignments which will have to do with water-power legislation will be altered under the organization of the coming Congress. The legislation, which has been in the hands of Democratic leaders in the House, will now be in charge of Republican leaders, inasmuch as the Republicans have control of the new House.

"American Welding Society" to Be Organized

A meeting at the Engineering Societies Building, New York, will be held March 28, 1919, at 10:30 A. M. to effect the organization of the "American Welding Society." It is planned to replace the Welding Committee of the Fleet Corporation and the National Welding Council, and by contributing memberships represent the manufacturers and users of welding equipment and products. Other engineering societies will be invited to participate in such a way that the American Welding Society will become a common section to consider such problems rather than a separate technical organization. To the welding public it hopes to become a dependable source of information, and, granted the necessary support, to pursue various desirable investigations in an impartial manner.

German Requisitions in Poland

The following table taken from the official reports of the German Central War Bureau shows some of the requisitions of the Germans in Poland during the period August, 1915, to the end of 1917, i.e., not including the year 1918, when all their sources were exhausted and when in the latter part of that year they were forced to leave the country and became more unscrupulous than ever:

	Tons		Tons
Metals (among them 7,000 of copper and 910 tons of steel cable)	18,140	Rubber	400
Iron	24,292	Asbestos	105
Prepared leather	1,718	Varnish and oil colors	14
Tanned leather	6,500	Tallow	221

Magnetic Concentration of Pyrrhotite Ores*

Experiments and Tests Made With a Wetherill Type Magnetic Separator on Pyrrhotite Ore—No Classification Necessary, but Should Be Stage Crushed to Unlock the Sulphides From the Gangue—Costs, Low—Quality, Satisfactory

By J. P. BONARDI
Assistant Chemist, Bureau of Mines

PYRRHOTITE ores have been utilized in the United States for the production of sulphur in the manufacture of sulphuric acid, and when the resulting cinder was sufficiently high in iron and free from objectionable substances it was employed directly in the manufacture of iron. Since the war, the importance of increasing all available sources of material going into acid production has brought pyrrhotite ores and methods of their concentration to the attention of the U. S. Bureau of Mines. The use of pyrrhotite ores in the past was limited, in that a high-grade ore or product was required and also one freed from those gangue substances which would cause trouble subsequently in the sulphur burners, and later would cause the cinder to become penalized in its use for iron smelting. This fact necessitated concentration of some sort, and when hand sorting was resorted to, considerable amount of sulphur-bearing rock was discarded, thus curtailing production and increasing the mining cost.

It was while investigating the pyrrhotite deposits of southwestern Virginia that Mr. R. R. Hornor, of the U. S. Bureau of Mines, observed that much of the ore contained 20 to 30 per cent gangue material, composed chiefly of granular silica and magnesia and lime bysilicates of the amphibole group, together with black mica. The presence of these impurities is objectionable in material for sulphuric acid manufacture for the following reasons:

1. They lower the sulphur content, and considerable quantity of the ore is discarded which will contain around 20 per cent sulphur, thus curtailing production and increasing the mining cost.

2. The capacity of the roasting furnaces is reduced by the quantity of inert material contained in the ore treated.

3. The lime and magnesia present, upon roasting, form sulphates of these minerals and thus reduce the quantity of sulphur available for acid making.

4. The impurities reduce the iron content of the resulting cinder, and also make it less desirable for iron furnaces.

Magnetic Concentration Suggested

It was suggested that the quality of ores containing these objectionable impurities might be very much improved by eliminating a large part of the impurities by some method of concentration; and, therefore, magnetic concentration has suggested itself as possibly the most suited for the purpose, owing to the slightly magnetic properties of the pyrrhotite, and also since the methods which would be employed to prepare the ore for roasting, namely, dry crushing and screening, would obviously leave the material in an ideal condition for magnetic separation.

In accordance with the program of increasing all available sources of sulphur material, it was suggested to the General Chemical Co. of Pulaski, Virginia, producer and refiner of pyrrhotite ores, that it ship large samples of its pyrrhotite material to the Rocky Mountain Station of the U. S. Bureau of Mines for investigation. Two samples of ore were received at this station. One sack consisted of ready crushed material, such as the General Chemical Co. is using at the present time in its roasting furnaces, that is, ore from the finished product bins; the other consisted of large lump size discarded ore from the company's mines.

The following data comprise work done, first, upon the discarded ore, and, second, on the finished product such as the company is now roasting, the object being, in both cases, to attempt to overcome some of the difficulties as outlined above by eliminating the gangue material, and to produce a high-grade concentrate of iron and sulphur from the discarded ore and also from the finished product material. The gangue material in both samples consisted of amphiboles, quartz and biotite.

Discard Ore From the Mine—Part I

The discarded ore as received in large lumps was crushed and finished off in a small "coffee mill" so as to stage crush all material through a 10-mesh screen. A screen analysis of this product through the 10-mesh gave the following results:

—10+20	28.60 per cent
—20+40	34.30 per cent
—40+80	21.00 per cent
—80	16.10 per cent
	100.00 per cent

Since the material was to be submitted for dry magnetic separation, fine grinding was to be avoided as much as possible, as the screen analysis indicates. It has been found by previous work on magnetic separation on roasted pyrite and pyrrhotite material that no practical concentration could be made on screened material which passed through a 100-mesh sieve. When the proper amperage was found which would render the coarse sizes below 100-mesh magnetic, and produce a proper concentrate with the required concentration ratio, it would, when applied to the finer sizes, render them practically totally magnetic; that is, 90 per cent or more, thus effecting no practical concentration of the values, when a concentration ratio of, say, 2 to 1 was desired in order to produce a high-grade product and recovery. This was due to the fact that on such fine ma-

*Published by permission of the Director of the U. S. Bureau of Mines.

terial the magnetic portion would carry off mechanically the non-magnetic fine gangue material.

Five runs were made upon the discarded material, using an experimental type Wetherill magnetic separator having a 6-in. belt and two double pole magnets. One run was made on each of the four screened sized products, and one on the unclassified material as ground, without any sizing, but stage crushed through a 10-mesh.

An analysis of the discard ore, as received and prepared for analysis, gave the following analytical results:

S	19 50 per cent
Fe	33. 45 per cent
Insoluble SiO_2	32 30 per cent
MgO	3 91 per cent
CaO and CuO	Small percentage

The composition of pyrrhotite is represented in text books by:

$Fe_n S_n + 1 \cdot Fe_6S_7$ to $Fe_{11} S_{12}$

1. Fe_8S_7	S = 40. 11 per cent	Fe.....59. 89 per cent
2. $Fe_{11}S_{12}$	S = 38. 51 per cent	Fe.....61. 49 per cent

From the analysis of the discard ore, and considering the proportion of iron to sulphur in pure pyrrhotite, it would indicate that some iron exists in the ore in some other form than is combined in the form of pyrrhotite. Assuming that the total iron and sulphur together make up a magnetic product, there would be represented 52.95 per cent (33.45 + 19.50) of the material magnetic, or a concentration ratio to be obtained for an ideal product of approximately 2 to 1.

Three Ampere Current Adopted

Qualitative runs were first made using different strengths of current by one-half ampere steps from 0.5 ampere to 5 amperes. This was tried on the unclassified material, as well as on the classified screened product, and the results indicated that amperage from 0.5 to 2 would take off only a small percentage of magnetic material. At 2 amperes, the magnetic product was found a little cleaner from gangue material than the product obtained at 2½ or 3 amperes, but the recovery was lower, since a considerable amount of pyrrhotite was still left behind in the non-magnetic tails. Three amperes was finally adopted as the best to employ on this experimental machine from the standpoint of economy and recoveries. At this amperage only a very small amount of gangue, principally biotite, would come off with the pyrrhotite. Higher amperage than 3 took off magnetically a considerable amount of gangue material with a small additional amount of pyrrhotite, which indicated that considerable gangue material was more susceptible to the magnetic forces than the very small amount of pyrrhotite which, in every case, was not attracted by the magnets. Undoubtedly, a slightly higher recovery could be obtained by employing a larger current than 3 amperes, but the grade of concentrate would be considerably lowered by more gangue matter being lifted off with the magnetic product.

The following table indicates the amount of material which was collected as non-magnetic on the different runs at 3 amperes:

Run	Size Stage crushed	Amount Taken	Non-Magnetic	Per Cent Non-Magnetic	Per Cent Magnetic by Difference
I	through 10-mesh	3000 g.	1420 g.	47 33	52 66
II	—10+20	2000 g.	980 g	49 00	51 00
III	—20+40	2000 g.	900 g.	45 00	55.00
IV	—40+80	100	620 g.	62 00	38.00
V	—80	10	320 g.	32 00	68.00

An average of the amount of non-magnetic material in the first four runs would represent 49 per cent, or a magnetic product of 51 per cent, which approximates very closely to the amount as figured as magnetic from the chemical analysis of the iron and sulphur; that is, a concentration ratio of approximately 2 to 1. On the finer size, —80 mesh, 68 per cent would be rendered magnetic, but since this size represents only 16 per cent of the material, the amount of gangue taken off would not in any case prove very detrimental to the grade of concentrate made on unclassified feed; that is, material stage crushed through the 10-mesh.

The following tables represent the runs made; the recoveries are stated later in a separate table:

RUN I UNCLASSIFIED DISCARD ORE AS GROUND THROUGH 10-MESH

Sample	Weight in Grams	Per Cent Insoluble (SiO_2)	Per Cent Iron (Fe)	Per Cent Sulphur (S)	Per Cent MgO
Head	3000	32 30	33.45	19.50	3. 91

Tails	620	.....	14. 38	7. 39	....
Mechanical loss	....	.....	.....	.....	....

RUN V —80 MESH

Sample	Weight in Grams	Per Cent Insoluble (SiO_2)	Per Cent Iron (Fe)	Per Cent Sulphur (S)	Per Cent MgO
Head	1000	29. 80	36. 20	21. 75	3. 11
Magnetic conc	650	19. 80	40. 40	26. 25	3. 22
Tails	320	... .	22. 40	13. 56	....
Mechanical loss	30	... .	.	.....	....

In the above runs, the losses figured as mechanical can be calculated with the magnetic concentrates. This loss occurred at the hoppers in collecting the magnetic material. Whatever loss there was in weight, if any, in collecting the tail discharge would be due only to dust loss, which was of no consequence on the material treated. On continual commercial runs the mechanical losses could be practically eliminated.

In the following table of recoveries of sulphur and iron for the different runs, the basis of calculation was derived by the amount of sulphur and iron remaining in the tails divided by the amount of sulphur and iron going into the heads, which represented the per cent of sulphur and iron going into the tails; the difference between this per cent and 100 per cent gave the recovery of sulphur and iron going into the concentrate.

In calculating the per cent elimination of insoluble (SiO_2) and MgO going into the non-magnetic tails, the per cent remaining in the magnetic concentrates was found (the mechanical loss was figured in as concentrates) and this per cent subtracted from 100 per cent,

giving the per cent of elimination of insoluble (SiO_2) and magnesia (MgO).

RECOVERY OF SULPHUR AND IRON IN MAGNETIC CONCENTRATES
Elimination of Insoluble (SiO_2) and Magnesia (MgO) in Non-Magnetic Tails

Run	Per Cent Recovery of S	Per Cent Recovery of Fe	Per Cent Elimination of SiO_2	Per Cent Elimination of MgO
I Unclassified	88 00	84.65	91 84	84.10
II —10+20	95 67	91.77	82.24	77.55
III —20+40	89.64	87.75	89.75	92.94
IV —40+80	74 50	73.60	96.06	95.56
V —80	80 05	80.20	54 80	29.60

The percentage recovery of sulphur for classified feeds, as in runs II to V if the screen products were run separately as classified feeds, would effect a saving of 84.5 per cent.

The above results clearly indicate that the run made on the unclassified material compares favorably with the screen-classified runs. A slight additional gain in per cent of recovery of sulphur and iron would not in any case be sufficient to install or operate a system of screen classification. Therefore, no classification would be considered justifiable in treating this material on the Wetherill machine.

Conclusions of Results on Discard Ore From the Mine—Part I

1. A high-grade concentrate can be produced from the discard ore from the mine containing less than 7 per cent total of gangue material, consisting chiefly of insoluble matter with a small amount of magnesia oxide, giving a recovery between 85 and 90 per cent of the values sulphur and iron.

2. Approximately 90 per cent of the gangue material can be eliminated with the non-magnetic tails.

3. The concentration ratio between heads and concentrates is about 2 to 1.

Finished Product Ore—Part II

The following data comprise work done upon the ready crushed material or finished product which is being used at the present time in the roasting furnaces, the object of the tests being the same as given with the discarded ore, namely, to eliminate the gangue, since this material also has given some trouble in the sulphur burners in the past due to the same impurities as in the discarded ore, namely, amphibole silicates, quartz and biotite.

The material as received gave the following screen analysis:

+20	23.33 per cent
—20+40	34.66 per cent
—40+60	14.66 per cent
—60+100	11.66 per cent
—100	15.33 per cent
Loss	0.36 per cent
	100.00 per cent

An analysis of the material is as follows:

S	27.51	75.61 per cent
Fe	48.10	
Cu	Trace	
Al_2O_3	2.82	24 39 per cent
SiO_2	12.40	
CaO	0.43	
MgO	1.74	
Undetermined	7.00	
	100 00	

The material was tested for soluble sulphates or sulphur minerals other than sulphides by a sodium bicarbonate and an ammonium carbonate leach, and the results indicated none present.

The above sulphur of 27.51 per cent would then correspond to 41.10 per cent Fe in the first formula as given for pure pyrrhotite (Fe_6S_7) and 43.90 per cent Fe in the second formula as given for pure pyrrhotite ($Fe_{11}S_{12}$), thus indicating that in the material containing 48.10 per cent Fe there must exist some iron in the form of an oxide, which presumably can be calculated with the undetermined portion, or possibly gangue material associated with the other oxides and silicates. Considering the analysis, it is easy to ascertain that if the total iron and sulphur is calculated as being magnetic and the remaining elements as non-magnetic, there would be then represented 75.61 per cent magnetic and 24.39 per cent non-magnetic substances. It is safe to assume that a concentration ratio of approximately 10 to 7.5 will collect the iron and sulphur into a magnetic product with a good recovery.

The following table indicates the amount of material which was collected as non-magnetic on the different sized products at 3 to 5 amperes:

TABLE I.

Run and Amperage	Size	Amount Taken, G.	Non-Magnetic, G.	Per Cent Non-Magnetic	Per Cent Magnetic by Difference
I 3 amp.	+20	2000	445	22.25	77.75
I 5 amp.	+20	2000	200	10.00	90.00
II 3 amp.	—20+40	2000	750	37.50	62.50
II 4 amp.	—20+40	2000	215	9.95	90.05
III 3 amp.	—40+60	1500	470	31.68	68 32
IV 3 amp.	—60+100	1000	310	31.00	69.00
V 3 amp.	—100	1500	70	4.67	95.33
and IX 4 amp.	—100	500	10	2.00	98.00
VI 3 amp.	Original material as received	3000	760	25.33	74.67
VII 3 amp.	Original material as received	3000	895	29.86	70.12
VIII 3 amp.	Material as received with —100 screened out	1200	335	27.90	72.10

From the above data, it is very apparent that 4 or 5 amperes current would be too large to employ, since on the coarse material (20-mesh) 10 per cent would remain non-magnetic, and on the —100-mesh material only 2 per cent would remain non-magnetic; both would be less than was calculated on the percentage of non-magnetic substance in the original material as received. A concentration ratio of 10 to 9 would prove insufficient to eliminate the gangue matter, so 3 amperes was then considered as probably the best to employ in most cases on the material as received and on the sized material, since this would give approximately the desired concentration ratio. In every case tried, 1 ampere proved insufficient, as only a slight amount was rendered magnetic. The following represents the runs made—the recoveries are stated in a separate table:

RUN I +20 MESH—AMOUNT TAKEN, 2000 G.

		Per Cent Sulphur
Head sample		30.85
Wt. of Products, Grams		
2 amperes	330	33.65

	1200	

RUN IX (SAME AS RUN V) —100 MESH—AMOUNT TAKEN, 500 G.

		Per Cent Sulphur
Head sample		26.10
	Wt. of Products, Grams	
2.0 amperes	345	25.50
2.5 amperes	70	27.75
3.0 amperes	35	25.13
4.0 amperes	10	23.75
Non-magnetic (tails)	10	19.50
Mechanical loss	30	
	500	

Efficiency Easily Calculable

The mechanical losses can be accounted for because of the difficulty in collecting all the magnetic products, as some did not fall in the hoppers, also because of some dusting and trouble experienced with the feed box not working properly. The recoveries figured on the heads minus the tails would be representative of the efficiency, as no trouble was found in collecting the non-magnetic portion.

TABLE II ANALYSIS OF NON-MAGNETIC TAILS

Run	Mesh	Per Cent Sulphur	Per Cent Iron	Per Cent CaO	Per Cent MgO	Per Cent SiO_2
I	+20	14 54	18.35	1.15	3.84	59.30
II	−20+40	13.36	14 45	2.11	4 16	54 75
III	−40+60	18.00	27.45	1.58	4.42	36 75
IV	−60+100	18.85	28 25	1.79	5.18	31.30
V	−100	22 80	Not determined			
VI	Original	17.43	26 70	1 70	4.66	35.70
VII	Original	18 90	30.67	1.44	3.48	37.80
VIII	+20+100	18.43	28.55	1 89	4.30	34.90
IX	−100	19.50	Not determined			

Result of Analysis

The analysis was not made on tails of Runs V and IX, because this represented runs made on —100-mesh material; and referring to Table I we see that there was no practical concentration ratio, since at 3 and 4 amperes only 4.67 per cent and 2 per cent respectively remained in the non-magnetic tails. Referring to Table II, it would appear that Run I on 20-mesh material and Run II on —20+40-mesh material gave the best tails, cleaner in sulphur and iron than on the other runs.

However, the analysis on these runs cannot be compared with the others, since the tails were produced by employing as high as 5 amperes on Run I with 10 per cent non-magnetic substance and 4 amperes on Run II with 9.95 per cent non-magnetic material. Also an analysis made on the magnetic products of these two runs show that they are contaminated with more gangue material.

Three Amperes Best for Comparison

The basis of comparing the results obtained on the classified sized material and the original sample is best found at 3 amperes.

Referring to Table I and the analysis of products of the respective runs conducted at 3 amperes, the following table is derived for a basis of comparison.

TABLE III ANALYSIS OF NON-MAGNETIC TAILS

Run		Per Cent Non-Magnetic at 3 Amp.	Per Cent Sulphur in Tails at 3 Amp.	Per Cent Iron in Tails at 3 Amp.	Per Cent SiO_2 in Tails at 3 Amp.
I	20 mesh	22.25	20.49	Not determined	
II	−20+40 mesh	37.50	23.51	Not determined	
III	−40+60 mesh	31 68	18.00	27.45	36.75
IV	−60+100 mesh	31.00	18.85	28.25	31.30
VI	Original mesh	25.33	17.43	26.70	35.70
VII	Original mesh	29.86	18.90	30.67	37.80
VIII	+20+100 mesh	27.90	18.43	28.55	34 90

The above results clearly indicate that at 3 amperes the results obtained on the original material as received compare favorably with the screen-classified runs. Therefore, no classification would be advantageous in treating this material on the Wetherill machine. As was previously stated in this paper, 3 amperes was found best to employ on the discarded ore also.

Recovery Results Tabulated

The following table will show in detail the results retabulated on runs made on the finished product material as received, with the percentage of recovery figured on the sulphur and iron that remained in the tails.

Since the results obtained on unclassified material compared favorably with any of the classified material, only the recoveries on these runs will be considered.

TABLE IV RESULTS OBTAINED ON MATERIAL AS RECEIVED ON WETHERILL MACHINE AT 3 AMPERES

		S	Fe	CaO	MgO	SiO_2	Per Cent Recovery S	Per Cent Recovery Fe
Run VI...	Heads	27.51	48.10	0.43	1.74	12.40	.....	.....
	Conc.	31.20	55.40	nil	0.83	4.30	83.96	86.00
	Tails	17.43	26.70	1.70	4.66	35.70	16.04	14.00
Run VII Duplicate	Heads	27.51	48.10	0.43	1.74	12.40	.....	.....
	Conc.	31.85	35.80	nil	0.94	3.85	80.00	80.97
	Tails	18.90	30.67	1.44	3.48	37.80	20.00	19.03

RUN VI

72.90 per cent of the total silica (SiO_2) remained in the non-magnetic tails
100.00 per cent of the total lime (CaO) remained in the non-magnetic tails
61.90 per cent of the total magnesia (MgO) remained in the non-magnetic tails

RUN VII (Duplicate, run same as VI)

90.60 per cent of the total silica (SiO_2) remained in the non-magnetic tails
100.00 per cent of the total lime (CaO) remained in the non-magnetic tails
59.70 per cent of the total magnesia (MgO) remained in the non-magnetic tails

From the average of the above two runs and the foregoing data, the following can be drawn:

Conclusions for Finished Product Ore—Part II

1. That from 80 to 84 per cent of the sulphur can be recovered, from 80 to 86 per cent of the iron can be recovered to form a high-grade concentrate.

2. That from 72 to 90 per cent of the total silica can be removed, 100 per cent of the lime and about 60 per cent of the magnesia.

3. It is apparent that the gangue that collects in the concentrate is either picked off mechanically, due to the —100-mesh material, or else is more magnetic than the pyrrhotite that remains in the non-magnetic tails.

4. The best working amperage would be between 3 and 5, depending upon the grade and fineness of concentrate; on this particular experimental type machine, 3 appeared the best to employ on the unclassified feed. The concentration ratio is approximately 10 to 7.5.

General Summary

1. The experiments and tests have proved that pyrrhotite ores of the grade received can be successfully treated by magnetic separation. Whether a company is justified in installing several machines depends upon the extent of the ore deposit and the demand for sulphide ore.

2. No classification of the ore is necessary, but it should be stage crushed enough to unlock the sulphide mineral from the gangue. On the ore treated stage crushing through a 10-mesh proved satisfactory.

3. The cost of treating a ton of material which would require no classification would be less than $1, and would possibly approach a few cents, depending upon the number of machines in operation, since one tender and a helper can easily take care of ten machines when in operation. A commercial size machine would probably treat between 5 and 10 tons of material per day. The depreciation of a Wetherill type magnetic separator is very slight, and the cost to operate would be covered by the cost of power going to magnets (3 amperes by 110 volts) and the power for motor operating machine. The capacity of any magnetic separator depends upon so many variables that it is impossible to estimate the exact tonnage until a test run has been made on a commercial size machine.

4. The grade of concentrate produced from the discard ore is superior to the grade received as finished product ore, and is equal to the concentrate obtained after treating the finished product material.

In conclusion, the author wishes to express his appreciation and gratitude to Dr. R. B. Moore, superintendent of the Rocky Mountain Station of the U. S. Bureau of Mines, and Dr. S. C. Lind, acting superintendent, for their valuable advice and instruction throughout the progress of the work.

The Engineer as a Citizen

What promises to be one of the most important meetings ever held by the New York sections of engineering societies will convene in the auditorium of the United Engineering Societies Building, Wednesday, March 26. The meeting has been arranged under the auspices of the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the Society of Automotive Engineers. The Electrical, Civil and Chemical Engineers as well as the American Chemical and Electrochemical Societies and other related organizations have been invited to participate.

The subject for the symposium is "The Engineer as a Citizen." It will be discussed under five heads, viz.

The Civic Responsibility of the Engineer. Philip N. Moore, A. I. M. E.

The Relation of the Engineer to Legislation. Calvert Townley, A. I. E. E.

The Relation of the Engineer to Administration. Nelson P. Lewis, A. S. C. E.

The Relation of the Engineer to Public Opinion. Spencer Miller, A. S. M. E.

The Relation of the Engineer to Production and Distribution. Comfort A. Adams, A. I. E. E.

National Association for the Protection of American Rights in Mexico

Representative groups of industrial concerns operating or having interests in Mexico have recently organized an association for concerted action to protect their own property and to promote friendly relations between the United States and Mexico. The function of the association will be to collect data regarding conditions in Mexico and be prepared at all times to furnish information to the Government of the United States and the American public. It will endeavor to keep constantly in touch with both Governments and assist wherever possible in removing causes of friction. It is particularly emphasized that the purpose of the association is not to bring our Government into conflict with Mexico but to promote stability in the latter country and confidence in our own. Thus far the association is composed of petroleum producers, bankers and security holders, mining and smelting companies, agricultural and other interests. Business organizations having interests in Mexico are invited to join the association. Mr. Frank L. Silsbee is secretary, and is located at Room 2800, 120 Broadway, New York City.

Work of the United States Employment Service

During the eight weeks ended Feb. 22, the United States Employment Service received 1,090,124 applications from men and women for jobs. Of this number 930,029 were referred to opportunities and 679,513 were reported placed in employment. The difference between the number referred to jobs and the number reported placed is due in a large measure to the failure either of the employee or employer to send in their return cards. Unless these return cards are received, the Service has no record of whether the prospect has received employment or not.

Observations on Flaky and Woody Steel

Discussion of the Causes of This Troublesome Defect in High-Grade Alloy Steels by the Eminent Italian Ironmaster—Methods Are Outlined by Which Flakes and Woody Structure Have Been Brought Under Complete Control in Ansaldo's Works

By DR. FEDERICO GIOLITTI
General Manager of Steel Works, Giov. Ansaldo & Co.

I WAS very much interested in the discussion of flaky and woody structure in steel which took such a prominent part of the recent meetings of the American Institute of Mining Engineers. In Italy we are much interested in such defects, especially at the Ansaldo works, where about two-thirds of the guns used by the Italian Army were made. Our output was expanded many times in the last four years, in the face of a great lack of old and skilled workmen, so that during the war we manufactured more than 10,000 guns, with complete mountings. The defects known as flakes and woody structure have been known to us for some time, and we have done much experimental work which has enabled us to eliminate them almost entirely. The practical result of this experimental work was that none of the gun forgings manufactured in our works have been rejected on account of woody or flaky structure.

Our experience agrees roughly with the last paragraph of the résumé published in CHEMICAL & METALLURGICAL ENGINEERING for March 1, 1919 (page 219), except that we believe they are not formed as cracks in the ingot. Therefore we would state these sentences: "Flakes originate in tender alloy steels as intercrystalline cracks, probably intensified by inclusions and segregations. They can consequently be controlled by careful steel furnace practice, casting, soaking, reheating, forging and heat treating."

Choice of Raw Materials Important

Ansaldo's gun forgings are of acid open-hearth steel exclusively, made from the highest grade pure puddled iron and a very pure electric furnace pig produced in our own furnaces at Aosta from Alpine magnetites. We insist that phosphorus and sulphur be held at an extreme minimum. Of even greater importance, however, we feel that free iron oxide (scale and rust) be kept at the lowest possible point in the raw materials charged in the furnace. This refers to scale on the surface of the metal (rusty turnings and borings are never used) and free oxide in the puddled iron itself. Thus a pure wrought iron will contain considerable iron silicate as intercrystalline streaks which is not detrimental, but an impure Lancashire iron containing free oxide may not be used.

Starting from this pure iron, extreme care is used to prevent superficial oxidation during melting by maintaining a reducing flame in the open-hearth furnace at all times. The slag covering is very thin, consisting only of silica combined with the fluxed impurities in the original iron; it is maintained so that test buttons show a clear glass, of a straw yellow color. We refine very hot; some 20 min. before pouring, shoveling into the furnace sufficient ferrochrome to produce the required analysis. At this time the condition of the metal and slag should be such that very little chromium is lost—one sign of good metal is that a 0.60 per cent chromium bath should produce not less than a 0.57 per cent chromium ingot.

Hot Pouring Preferred in Europe

Contrary to Dr. Howe's recommended practice, we pour very hot. Our forging ingots are all fluted octagons, and our observations show that flakes, when they occur, have no habitual location or direction. The hot steel is cooled to 600 deg. C. in the mold, then stripped and left in the air. The cold ingot is then reheated just before forging to 1200 deg. C. as a maximum and the forging continued to a dull red heat. The large dendritic crystals formed in hot-poured ingots require care and skill in forging, it is true, but when rightly done such steel produces superior results, and so it has become a saying in our plants that when the outer part of hot-poured ingots has a tendency to crack under forging it is a sign of a good heat, and no rejections will occur.

Chromium Steel, Properly Made, Will Not Develop Flakes

What I wish to emphasize is that chromium steel, properly made of pure materials in this manner under reducing conditions and containing no oxide, will never develop flakes. When so made you can pour it into an ingot of any cross-section and forge it as you like—either fast or slow, with reheating or without, with great or slight reduction (always providing the work is done within the correct temperature limits and with usual skill)—and flakes will not appear. We have made a large number of complete experiments to prove this point, using many types of ingots, then forging and treating them in many different ways for making different sizes of gun forgings. I have in my office complete records of these experiments, which I hope to be able to publish later.

As an instance of our contention that, if the steel is properly made, flakes are not produced by mechanical work, I may cite the fact that in November, 1917, after the Austrian advance which cost us so many men and guns, we wished to produce gun tubes at a rate far beyond the capacity of our forging presses. We therefore took our good steel ingots, heated them to the correct temperature and rolled them in a blooming mill, reducing their diameter from about 1.050 m. to about 0.250 m. in this way, without reheating. I do not need to remark that this practice produces intermetallic changes about as different as can be imagined

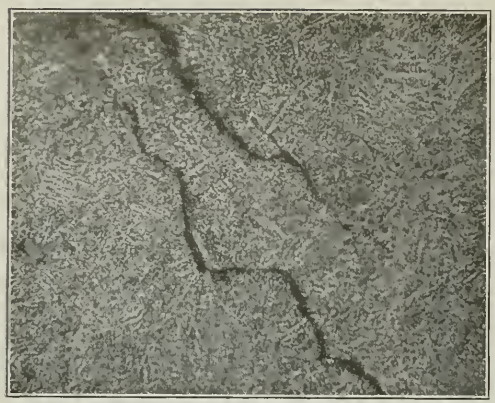

FIG. 1. FLAKES IN HEAT TREATED NICKEL-STEEL FORGING. AFTER RAWDON. × 500

from that by forging, yet not a single instance of woody or flaky structure resulted. After the pipe was cropped off, the balance of the piece was perfectly sound, as was established by numerous tests in all parts of the section. It was then bored and turned to dimension, and the resulting ordnance was satisfactory in all respects.

Oxidized Inclusions Responsible for Flakes

On the other hand, a bath of metal properly made from correct raw materials will develop woody structure excessively if only a few kilograms of scale are thrown into the furnace even a long time before tapping. Microscopic examination of this defective metal seldom reveals an increased amount of inclusions, still we feel that this "oxidized metal" is flaky by virtue of its content of emulsified iron oxide, or some substance produced thereby which has diffused or broken up beyond the detection of a microscope. If rusty scrap or turnings are melted, the chances for rejection are increased enormously. Again, we found trouble as soon as the raw materials available were of inferior grade.

Such experiences as these convince us that flaky and woody structure, which two defects are near relatives, occur in steel containing highly oxidized inclusions. Usually these are beyond the power of the microscope to detect, yet sometimes larger non-metallic inclusions are found associated with flakes, as shown by Mr. Rawdon. The action of such larger segregations may be studied, and throw considerable light upon what I regard as the ultimate cause of flakes.

Theory of Cause of Flaking

It is necessary to explain why non-metallic inclusions are often surrounded by decarbonized zones—when this is explained the cause of flaking is also found. It certainly is not due to Ziegler's idea that ferrite, in being rejected from hypoeutectoid austenite, collects around the slag as a nucleus. Crystals usually form about points of like crystalline shape—ferrite grows upon ferrite, or upon isomorphous metallic substances. It seems to me that the presence of ferrite near a slag inclusion is due rather to a decarbonization caused in a manner somewhat like the following:

There exists in slowly cooled clean steel (normalized steel) a considerable quantity of gas in solution, such that a substantial equilibrium exists between the system $Fe : Fe_3C : CO : CO_2$ according to the following equation

$$3Fe + 2CO = Fe_3C + CO_2$$

The gases CO and CO_2 are occluded or dissolved in the metal (among other gases as well) in such a manner that no cavities are found, even ultra-microscopic. A similar equilibrium condition of an oxidizing slag may readily change with changing temperature in such a way that an excess of CO_2 is transferred into the metal, unbalancing the equation given above and shifting it to the left, actually producing a zone of decarbonized iron in that vicinity, somewhat supersaturated with CO gas as well.

In this manner appears a spot of ferrite about an oxidized nucleus. On working, it flattens out into a thin sheet, perfectly continuous with the metal behind it and only separated at perhaps a minute point in the very center. But the flake is not in the real sense an internal crack—the crack with the characteristic bright flaky appearance does not exist until the piece is strained beyond the elastic limit of the surrounding unaffected metal. When this stronger metal stretches it throws a concentrated stress on the weaker ferrite spots, which forthwith fracture.

Discussion of Theory

The following simple experiment is cited to sustain my theory of flake-formation. Take a piece of steel in which decarbonized zones surround a slag inclusion, and heat it to 1000 deg. C. in an atmosphere of CO for some 24 hours. On re-examination, the inclusion is no longer surrounded by ferrite. Again heat the sample, but this time in CO_2, and the ferrite envelopes reappear. In the first case the excess CO in the surrounding atmosphere overwhelms the CO_2 from the inclusion, and the region is carburized; in the second case the preponderance of CO_2 in the slag inclusion is re-established and decarburization ensues.

All these matters have been discussed by me completely in different papers published in 1914 in "Zeitschrift für Metallographie," and in 1916-17 in "Metallurgia Italiana."

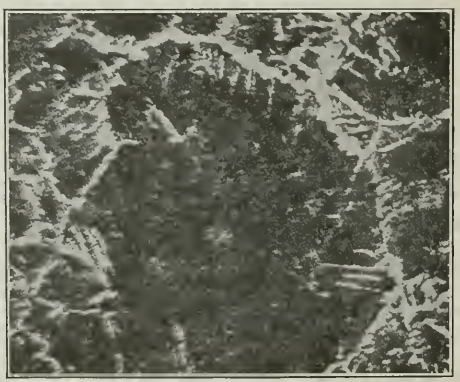

FIG. 2. FERRITE SEGREGATION IN HOLOCRYSTALLINE METAL. AFTER CLAYTON

Mr. Rawdon's sample (Fig. 1) is apparently of quenched metal, and the decarbonization along the flake (which does not need to be very deep-seated) is not in evidence. Should this specimen be annealed, it is probable the crack would then exhibit ferrite borders. Messrs. Clayton, Foley and Laney, on the other hand, showed lantern views where the crack is bordered by ferrite in coarse-grained metal something like the diagonal ferrite streak in Fig. 2. However, as can be seen from the preceding discussion, I differ from Mr. Clayton and his associates in that I believe the ferrite is due to invisible oxidized inclusions; the flake follows essentially these inclusions rather than true ferrite grain envelopes or Widmanstättian bands.

The fact that flakes are not found so frequently in carbon steels would support my hypothesis, since it is a well-known fact that carbon steels (under the same conditions) retain but few non-metallic inclusions as compared with these alloy steels.

Woody Structure Cured by Heat-Treatment

If my gas-theory be true, it should be possible to cure woody structure by heat-treatment, and this has indeed been done systematically in the Ansaldo works when the steel was not actually overloaded with highly oxidizing slag. Such defective material if heated to 1000 deg. C. in reducing atmosphere (largely to prevent surface oxidation) for perhaps 12 to 18 hours, will allow a complete equilibration of the gaseous atmosphere and a ferrite diffusion resulting in a more uniform carbon distribution. As a matter of fact a measure of highest quality in steel is the ease by which structure caused by forging or rolling may be obliterated by heat treatment. (It is easy to show that inclusions are much more important in their effect upon "inheritance" and the appearance of free ferrite than are the original dendrites. Thus a piece of polished heat-treated steel lightly etched with MCl will show the outlines of the original crystalline grains. Repolish and etch with picric acid, and photograph the younger crystals in exactly the same area. Superimpose these micrographs and the older crystalline outlines will appear to have little relation to the younger ones.) These questions are also covered in the papers already noted, and to a greater extent in a volume on "Heat Treatment of Low Carbon Steels," published last year in Italy and now in course of translation into French and English.

Woody Structure Reduced by Light Reduction

Again, woody structure, if not excessive, can be diminished by careful and light reduction at temperatures from 1200 deg. C. to 800 deg. C. The exact explanation of this fact is not clear, except perhaps that forging at low heat destroys Widmanstättian structure, and with it any ferrite cleavages.

My opinion is founded on a careful study of the effect of visible inclusions on the constitution of the surrounding metal, on the mechanical properties of the steel and on the appearance of the fractures. A long account of these observations has been published in the volume already quoted. It may be noted that flakes differing widely in size and extent are associated with visible inclusions of the same size—large inclusions, if non-oxidizing in nature, do not give rise to flakes, while very small inclusions can produce very large flakes if they have a highly oxidizing power. This oxidizing nature is revealed by the large areas of ferrite occurring around the inclusions in the slowly cooled metal.

These interesting and important matters I hope to discuss more at length upon my return to Italy, when I will have our original records and observations available.

New York City.

American Electrochemical Society, New York Meeting

THE program arranged for the American Electrochemical Society, which will convene in New York City April 3 to 5, gives promise of meeting fully the hopes and expectations of those who planned the symposium on "Released Information." Members of the society who have been engaged in important war work of a chemical and electrochemical nature are now permitted to write and talk about the processes on which they have been working. The sessions will be held in Rumford Hall, Chemists' Club.

The annual business meeting and election of officers will take place Thursday morning, April 3, and will be followed by a technical session for the discussion of papers. The afternoon will be devoted to the same purpose. In the evening there will be an illustrated lecture by Mr. W. S. Landis on the Oxidation of Ammonia to Nitric Acid.

Both morning and afternoon sessions on Friday, April 4, will be devoted to the symposium on "Released Information."

Tentative plans are under way for an all-day trip to the chemical and metallurgical plants at Perth Amboy on Saturday, April 5. With the close of the war social features will be in order again and Section Q will be revived at a smoker.

Following are some of the papers that will be presented:

Oxidation of Ammonia, W. S. Landis.
Notes on Electrostatic Precipitation, H. D. Braley.
A Process for Electrically Refining Nickel, G. A. Guess.
Principles of Inductive Heating With High Frequency Currents, E. F. Northrup.
Uranium, Gustave Gin.
Remarkable Pitting of Electroplating, O. P. Watts.
Electroplating Iron From the Copper Solution, O. P. Watts.
Nelson Electrolytic Chlorine Cell, C. F. Carrier.
Electrolytic Silver and Gold Refining at Perth Amboy, G. G. Griswold.

Symposium on "Released Information"

1. Edgewood Arsenal, W. H. Walker.
2. An Electrolytic Process for the Production of Sodium Permanganate From Ferromanganese, R. E. Wilson and W. G. Horsch.
3. Silicon Tetrachloride, O. Hutchins.
4. Silicon Tetrachloride and Titanium Tetrachloride Smokes, G. A. Richter.
5. Portable Electric Filter for Smoke and Bacteria, A. B. Lamb.
6. The Preparation of Fluorine, W. L. Argo, F. C. Mathers, B. Humiston and C. D. Anderson.
7. Lead Plating of Shell Interiors and Boosters, A. G. Reeve.
8. Electric Furnace Manufacture of Silicomanganese, B. G. Klugh.
9. Electric Furnaces Used in the Production of Essential War Materials, T. F. Baily.
10. Chemical War Secrets and Releasing Manufacturers' Reports, E. Gudeman.

Fusibility of Coal Ash*

The Interior Province Coals as Compared With West Virginia Coals — Relation of Fusibility Tests to Clinker Formation — Interpretation of Fusibility Tables — Tables of Data on Illinois, Indiana, Kentucky, Kansas, Missouri, Oklahoma, Arkansas and West Virginia Coals

By W. A. SELVIG, W. C. RATLIFF and A. C. FIELDNER

THE interior coal province, which includes all of the bituminous coal fields near the Great Lakes, in the Mississippi Valley and in Texas, contains a vast amount of coal which is extensively mined and has been a very important factor in the development of the great manufacturing centers of this region.

While there is a large amount of analytical data available as to the composition of these coals[1], there has been no general survey of the fusibility of the ash from the various coal beds. The fusibility of coal ash is of special interest to the consumer of coal in connection with the formation of clinker due to the melting of the ash constituents of the coal when fired under boilers. The Bureau of Mines is therefore making fusibility tests on the well-known American coals, and this paper gives a summary of such tests on the coals of the interior province, together with a comparison of similar tests on the well-known coals of West Virginia. A previous paper [2] gave a description of the standard gas-furnace method used by the Bureau of Mines in making ash fusibility tests, together with a summary of such tests on West Virginia coals.

Relation of Fusibility Tests to Clinker Formation

It is well to bear in mind that fusibility tests as made in the laboratory are not directly comparable to the conditions existing when coal is burned in a furnace, as in a laboratory test the impurities remaining as ash are intimately mixed, while there is no such uniform distribution when the coal is burned. Fieldner, Hall and Feild[3] have shown that in a laboratory fusibility test various factors have a great influence on the results obtained.

The standard gas-furnace method as used for the tests takes into consideration the different factors influencing the results obtained, with special reference to the atmosphere surrounding the ash during the test. With this method the atmosphere in which the ash is heated is readily controlled by burning an excess of gas, under which condition a reducing atmosphere is obtained by which the iron in the ash is reduced to the ferrous state, which gives the lowest temperature at which clinkering may result. This is of special importance in testing ash from coals of the interior province, as they contain a relatively large amount of iron in the form of pyrite. Consequently, higher softening temperatures may be expected in tests using oxidizing atmospheres by which the iron would be oxidized to ferric oxide, or in tests using strongly reducing atmospheres by which the iron would be largely reduced to the metallic state. In both of these conditions a more refractory and viscous slag is formed than would result if the atmosphere were such as to reduce the iron in the ash to the ferrous state, which gives the most fusible condition.

Analyses of clinkers from boiler furnaces indicated that the conditions were such as to form clinkers in which the iron is present principally in the ferrous state, consequently the values obtained in the laboratory tests are in this respect comparable to the actual fuel-bed conditions, and give the lowest temperatures at which the intimately mixed ash will soften with the formation of clinker.

Interpretation of Fusibility Tables

The tables of fusibility of coal ash tests give the average values for all mines tested in each coal bed. Average values for each mine were computed from the individual samples, which in practically all cases are standard mine samples collected by representatives of the Bureau of Mines, the United States Geological Survey, or by the various State geological surveys, according to the methods used by the Bureau of Mines[4]. A small number of car samples which were considered representative of the output of the various mines are also included.

The number of mines sampled and the total number of samples represented for each bed are given, as it is evident that the greater the number of mines sampled the more representative are the average values for the coal beds. This should be kept in mind, as in some cases the values given for the beds represent only a few mines and are then not truly representative of the coal bed.

The point taken as the softening temperature is that at which the ash when molded into solid triangular pyramids $\frac{3}{4}$ in. high and $\frac{1}{4}$ in. wide at the side of the base, and mounted in a vertical position, has fused down to a spherical lump. Points at which the tips of the cones first fuse and at which the ash become very fluid are also taken and serve mainly as an indication of

the viscosity of the melting ash; however, these values are not tabulated in the following tables. The average per cent ash and sulphur, on the dry coal basis, is given as a basis of comparison of the different beds.

Table I gives the various beds of the interior province arranged alphabetically under the different States, with the number of mines sampled, number of samples represented, average softening temperature in degrees F., per cent ash and per cent sulphur on the dry coal basis.

Coals from all the States included in the interior coal province with the exception of Michigan and Iowa are given, there being no available mine samples of coals from these two States when the tests were made.

In order to compare the values obtained for the coals of the interior province with some of the standard coals of the country, values for the coals from West Virginia are given in Table II. Among these coals are some of the highest grade and best known fuels of the country. The coal beds are arranged according to their geological succession, the uppermost beds being listed first. It will be noted that among the softening temperatures given for the beds of West Virginia are values preceded by a plus sign (+). This indicates that the true values are above those given. Ashes which did not fuse at 2830 deg. F., which was the highest temperature attained in the gas furnace method, were heated to 3010 deg. F. in a molybdenum-wire resistance furnace in an atmosphere of hydrogen; hydrogen being used in this type of furnace to prevent the oxidation of the resistance wire. Ashes softening above 2830 deg. F. have such a low iron oxide content that the nature of the atmosphere surrounding the ash cones during the test has little influence on the fusibility. In a large number of samples of ash from the West Virginia coals the ash remained unfused at 3010 deg. F. These values were marked plus 3010 (+3010) and used as such in figuring the average values for the mine from which the average values of the beds were computed.

Discussion of Fusibility Values

In general the softening temperature of coal ash from the various coal fields of the United States ranges from 1900 to 3100 deg. F. For convenience in discussion, the order of fusibility of an ash may be expressed by subdividing this range of softening temperature into three groups as follows:

Class 1, refractory ashes, softening above 2600 deg. F.

Class 2, ashes of medium fusibility, softening between 2200 and 2600 deg. F.

Class 3, easily fusible ashes, softening below 2200 deg. F.

West Virginia Coals

The West Virginia coals include representatives of all three classes of fusibility. On the basis of the average softening temperature of all mines sampled from each coal bed, it is found that with the single exception of the Lower Kittanning bed, all the beds of the Monongahela, Conemaugh and Allegheny series belong to Class 3. There are, of course, individual mines here and there, as, for example, in the Pittsburgh bed in Marion County, which come in the lower part of Class 2.

Almost all of the mines in the Pocahontas No. 3 bed in McDowell County and half of the mines in Mercer County belong to Class 2. The remainder are in the lower part of Class 1.

The ash of New River coal is largely in Class 1, the Sewell bed averaging over 2580 deg. F., as compared to 2460 deg. F. for the Pocahontas No. 3 bed of the Pocahontas coal. The other important bed of this field is the Beckley or War Creek, having a uniformly refractory ash averaging over 2800 deg. F.

In so far as tested the Kanawha coals comprising the Coalburg, Winifrede, Cedar Grove, No. 2 Gas and Eagle beds also show a very refractory ash. Very little if any clinkering should be experienced in using these coals.

Interior Province Coals

The coals from the interior province present a fusibility survey of entirely different aspect from that of West Virginia coals. With the exception of the No. 4 bed in Indiana and the Santo Tomas bed in Texas all the average fusibility values of the different beds are found between 1900 and 2200 deg. F. Furthermore, the fusibility of ash from different samples taken in the same mine usually shows comparatively small variation, averaging only 140 deg. F. in the mines represented in the table.

The low softening temperature of the ash from these coals is probably due to the pyrite, gypsum and calcite that occur so generally as impurities in coals from the interior province. A few mines producing low sulphur coal in the No. 6 bed of Franklin County, Illinois, belong to Class 2 as regards fusibility of ash.

In general it might be said that individual mines producing lower sulphur coal than the average sulphur values given for the bed in which they occur also gave higher fusibility of ash values than that indicated in the table for the bed.

Change in Method of Distribution of Bureau of Standards Standard Samples

THE Bureau of Standards reports that it is making strenuous efforts to renew its depleted stock of standard samples. The great increase in the demand for these samples from regular sources and extra calls from the inspection sections of the War and Navy Departments, together with the inability to get increased appropriations for this work, have made it very difficult to keep the supply adequate. The demands of the military branches of the Government have made it impossible to procure the material for the renewal of some of the samples and have made it difficult to procure the machinery for the preparation of the iron and steel samples. It may not be realized generally that the preparation of a Standard sample consumes about three-fourths of the time required for the entire work upon it.

The present method of distribution has been known for some time to be cumbersome. New ordering and shipping regulations have therefore been adopted and ordered published on two additional pages 5 and 6 of the Supplement to Circular No. 25, "Standard Samples—General Information." This new supplement will be ready for distribution about March 15, and can be obtained on request from the Bureau of Standards, Washington, D. C.

As adopted, these regulations provide for the ordering of standard samples by number and name from the list printed on the first page of the above-mentioned supplement just as at present. From this time forward all samples for points in the United States or its possessions will be shipped by parcel post, C.O.D. Those for points in Canada, Mexico and other foreign countries will be shipped by express, C.O.D. The regulations of the Department of Commerce require that the payments for these samples be in the hands of Government agents before delivery can be made. By using the parcel post exclusively the Bureau hopes to make it possible for customers to send in their orders and pay for them through their own post office when delivery is made. It is hoped in this way to make prompter shipments and avoid the necessity for refunds when samples ordered are out of stock.

The 10 per cent quantity discount heretofore given on four or more samples ordered at one time has been discontinued.

The Bureau has on hand at present a fairly adequate stock of the following:

Sample Number	Name	Constituents Determined or Intended Use	Weight of sample in grams	Fee per sample with certificate
1	Argillaceous limestone	Complete analysis	100	$1.00
2	Zinc ore D	Zinc	100	1.00
4b	Iron B	C, Si, Ti, P, S, Mn	150	2.00
5c	Iron C	C, Si, Ti, P, S, Mn, Cu	150	2.00
7	Iron E	C, Si, Ti, P, S, Mn, Cu, Cr, Ni, V	150	2.00
8b	Steel, bessemer, 0.1 C	C, Si, P, S, Mn	150	2.00
9b	Steel, bessemer, 0.2 C	C, Si, P, S, Mn	150	2.00
11b	Steel, B. O. H., 0.2 C	C, Si, P, S, Mn	150	2.00
12b	Steel, B. O. H., 0.4 C	C, Si, P, S, Mn	150	2.00
15a	Steel, B. O. H., 0.1 C	C, Si, P, S, Mn	150	2.00
16a	Steel, B. O. H., 1.0 C	C, Si, P, S, Mn	150	2.00
17	Sucrose	Calorimetric value and saccharimetric value	60	2.00
20a	Steel, A. O. H., 0.4 C	C, Si, P, S, Mn, Cu, Cr, V, Ni	150	2.00
21a	Steel, A. O. H., 0.6 C	C, Si, P, S, Mn, Cu, Cr, V, Ni	150	2.00
22a	Steel, bessemer, 0.6 C	C, Si, P, S, Mn	150	2.00
24	Steel, vanadium, 0.15 V	C, Si, P, S, Mn, V (Ni, Cr, Cu, Mo)	150	2.50
26	Crescent iron ore	Al_2O_3, CaO, MgO	100	1.50
27a	Sibley iron ore	SiO_2, P, Fe	150	2.00
28	Norrie iron ore	Mn (low)	100	1.50
29	Magnetite iron ore (titaniferous)	Full analysis	150	2.00
33	Steel, nickel	C, Si, P, S, Mn, Ni (Co, Cr, Cu, W, Mo)	150	2.50
34	Steel, A. O. H., 0.8 C	C, Si, P, S, Mn (Cu, Cr, Mo)	150	2.00
35	Steel, A. O. H., 1.0 C	C, Si, P, S, Mn (Cu, Cr)	150	2.00
37	Brass, sheet	Cu, Zn, Sn, Pb, Fe, Ni	150	3.00
38	Naphthalene	Calorimetric value	50	2.00
40	Sodium oxalate	Oxidimetric value	75	1.25
41	Dextrose	Reduction value	70 140	2.00 3.00
42	Tin	Melting point	350	2.00
43	Zinc	Melting point	350	2.00
44	Aluminium	Melting point	200	2.00
46	Cement (normal)	Testing sieves	160	.25
47	Cement (extra fine)	Testing sieves	160	.25

There are at present in course of preparation samples Nos. 6c iron D, 13b B. O. H. steel 0.6 carbon, 14b B. O. H. steel 0.8 C, 23a bessemer steel 0.8 C, 25a manganese ore, 30a chrome-vanadium steel, 31a chrome-tungsten steel, 32a chrome-nickel steel and 37a sheet brass.

Of these it is hoped to have Nos. 30a and 37a ready for distribution by April 1, 1919. Nos. 6c and 25a should be ready by June 1 and the others will follow as rapidly as facilities will permit.

Decomposition of Metals—I

A Critical Review of Various Theories Which Have Been Advanced From Time to Time to Explain the So-Called "Disease of Metal"—Allotropy, Recrystallization, Corrosion, and Season-Cracking May Each Be Responsible for Some Types of Such Failures

By COLONEL A. I. KRYNITZKY[1]

CONSIDERABLE popular attention has been attracted lately to the decay or decomposition of metals, although this is not new to technical literature. Thus, Messrs. Moissan and Ditte discussed the question of the decomposition of thin aluminium ware in the pages of *Comptes Rendus de l'Academie des Sciences* in 1898 and 1899. A very interesting study of the same decomposition was made by Ducru about twenty years ago, when he proved that such decomposition or self-destruction is accompanied by but very little chemical reaction or oxidation. Ducru examined under the microscope the parts which were in various stages of disintegration, and in some he noticed a nest of fire cracks. These observations were published later by H. Le Chatelier[2], who, as did Charpy and Heyn, also studied various stages of decomposition of soldiers' drinking flasks.

Ernst Cohen brought these questions to life again in 1910, basing his essay on the work of Dr. von Hasslinger[3]. The latter started his studies with an accidental discovery. He attempted to use a pump which had stood without use for two years, and he found that it could no longer maintain a vacuum. Upon careful examination he found that the tin (the pump was made of tinned iron, soldered) had cracked and had become crystallized in spots. Besides, the whole surface, previously bright, had a crystalline structure and a dull appearance. Hasslinger supposed at first that this was the so-called "gray modification" of tin, stable below 18 deg. C. This idea was disproved, however, by the fact that the temperature of the laboratory had never fallen below 19 or risen above 45 deg. C., as was noted by maximum and minimum thermometers.

"Disease" Communicated

To his great surprise Hasslinger further made a successful attempt to communicate this "disease" from the decomposing tin to some with a clean surface. Such "infected" pieces of tin, when kept at different temperatures (6, 19 and 37 deg. C.), exhibited a similar progressive decomposition, the surface becoming dull and crystalline in appearance, spreading in a circle from the point of infection at the rate of from 3 to 5 mm. a day, the speed decreasing as the distance from the center. Along the edges of such decomposed spots tiny cracks could be seen, and even beyond these cracks the tin was crystallized. The same results were obtained with the infection of tinfoil containing about 25 per cent of lead. In this case the decomposition penetrated the full thickness of the foil and the decomposed part fell to pieces when shaken. High temperature did not affect the condition of the tin until the melting point was reached. Decomposed tin became normal after being melted.

Hasslinger also found that the melting points of the decomposed and normal tin were different: 205 deg. C. for decomposed and 231 to 232 deg. C. for normal material taken not far from the damaged portion. It must be noted, however, that the pieces of decomposed tin could not be absolutely separated from the last traces of the normal metal.

Allotropic Modifications of Tin

It would not be out of place to mention some of the facts known in regard to the allotropic modifications of tin. These were observed by Erdman as far back as 1851. He noticed that tin organ pipes became decomposed in spots without any apparent cause—the surface of the metal became rough, swollen and covered with projections. After a sufficient length of time small grains of metal fell out, so that there finally appeared a hole in the wall of the pipe. Fritzche (Petrograd) described similar cases in 1869 and several others during the period 1870 to 1897. Ernst Cohen described a case where a large part of a billet of very pure white "Banca" tin had decomposed into a gray powder after it had been received in Moscow. The gray modification could easily be scraped off with the fingernail. The writer, together with Eng. Koroboff, observed similar cases with Banca tin in the Petrograd Time Fuse Works.

According to Farup, in the case of cast tin the decomposition may be prevented, or at least considerably delayed, by adding some antimony to the metal. He has shown that the alloying metals may be divided into three groups as follows:

1. Hg.
2. Zn, Cd, Cu, Ag.
3. Bi, Sb.

Mercury is practically inert in its effect. Metals of class 2 have a slight influence, increasing in degree from left to right as they are written. Metals of the third class retard the transformation considerably.

Authorities differ as to the cause of such decomposition. Some attribute it to low temperature; others to low temperature together with shaking or vibration, and some to the decomposition which follows more or less rapid cooling of melted tin. Cohen and Van Eijk found that at about 18 deg. C. white tin transforms into a modification known as gray tin. In other words, there exists at least two allotropic modifications of tin, viz., gray, which is amorphous and has a specific gravity

[1]Member of the Commission for Inspection of the Artillery Orders of the Russian Government and Chief Inspector of Time Fuses.
[2]*Revue de Metallurgie*, 1911, Vol. 5, p. 373: "Etude d'echantillons d'aluminium spontanément désagrégés, remis par M. Ducru."
[3]*Revue de Metallurgie*, 1910, No. 4.

of 5.8, stable below 18 deg. C., and white, which is crystalline, has a specific gravity of 7.2 and is stable at temperatures above 18 deg. C. The transformation was found to be reversible.

Transformation Requires Some Time

The phenomenon of the transformation of white tin into gray—the so-called tin "plague"—is very much like that transformation well known to chemists where brown sulphur reverts into the yellow modification when it is slowly cooled after melting. On account of a certain amount of internal friction the transformation from one crystalline form into another requires some time. Thus the yellow spots which appear on the surface of the brown sulphur grow very slowly. Likewise, when white tin is cooled below 18 deg. C. it does not become gray immediately, but tends to remain as the white modification in an unstable condition. This may be compared with the unstable condition of oversaturated solutions; crystallization (and transformation) ensues on the introduction of a small fragment of the solute (or on contact with a particle of the transformed material).

In addition to the change into amorphous gray tin at 18 deg. C., the tetragonal white crystalline modification stable at room temperature changes into a rhombic modification at 161 deg. C., as was proved by Degens[4], although previous investigations had placed this point at 200 deg. C. Trechman also determined the specific gravity of the rhombic tin to be 6.5 at 15.8 deg. C., while for the tetragonal tin at 15 deg. C. it was 7.2. Rhombic tin is very brittle; this explains a common method of producing tin powder, which consists of dropping tin when heated to about 200 deg. C. from a certain height upon iron plates.

The diagram, Fig. 1, represents different stages of the condition of tin, and graphically represents the following facts: At 18 deg. C. gray tin becomes white (tetragonal); at 161 tetragonal tin becomes rhombic; and rhombic tin melts at 232 deg. C. This cycle is reversible, and the dotted lines *df* and *c* indicate unstable conditions at ordinary temperatures.

Ernst Cohen[5] has carefully studied the allotropy of tin as well as of other metals. He discovered that the infection may be inoculated in tinfoil by means of the decomposed powder in such a way that it will show its effect on several thicknesses of the foil laid one on top of another. Cohen originally thought that he was witnessing simply a transformation of the normal tin with tetragonal crystals to the rhombic modification first described by Trechman and Foullon, as noted just above. This idea was disproved, however, by Hasslinger's temperature test, which showed that when infected tin was kept at different temperatures (7, 19 and 37 deg. C.) it continued to decompose.

A piece of tinned iron was infected in one spot and kept in a thermostat at 184 deg. C. After one-half hour, the decomposition was noticeably spreading further and continued even after twelve hours. The same result was obtained in a thermostat held at 161 deg. C., while uninfected tin did not show any change whatever under the same conditions. Similar tests proved that the progress of the infection was still noticeable at 230 deg. C. (very near the melting point, 232 deg.), so that such decomposition could not have been explained by the transformation of tetragonal tin into the amorphous gray modification.

Recrystallization of Copper and Tin

A new theory had to be advanced, and the following facts were taken as a basis. First, it has been proved that metal becomes more susceptible to electrolytic action if it has been drawn or forged. Forged metal is evidently in an unstable condition as compared with metal not forged. This can be seen from the fact that

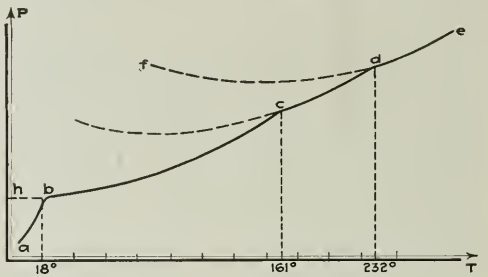

FIG. 1. ALLOTROPY OF TIN

in a galvanic battery composed of the forged and soft metals in a solution of a salt of the same metal, the forged metal becomes charged negatively and passes into solution. It is thought that the transformation of forge-hardened metal into a stable condition takes place even at ordinary temperatures, but at a very slow rate, so that it takes a long time before such transformation can be noticed. It proceeds more rapidly with rise in temperature, and also when the piece is brought in contact with the final (stable) modification.

A very good example of recrystallization was given by Baucke, who made the following experiment. He took two pieces of copper, hammered and annealed, respectively, and clamped their polished surfaces together. The combination was then heated to different temperatures successively, and it was found that at 105 deg. C. the hammered surface became considerably recrystallized. But when the surfaces were separated or insulated with an oil film there was practically no modification even after 48 hours at 180 deg. C.

The second basis for the new theory is derived from the ability of metals to change their crystalline structure. This means that the crystals can grow in size, which, as has long been known, takes place more rapidly with higher temperatures, although it appears probable that previous straining is a prerequisite to crystalline growth. Generally speaking, the following phenomena are included in the term "recrystallization":

1. Change in the form of the crystals (polymorphous crystallization).
2. Growth of small crystals.

[4] *Zeitschrift fur Anorganischen Chemie*, 1909, Vol. 63, p. 207. [5] "Physical Chemical Studies of Tin"; *Zeit. Phys. Chem.* Vol. 30, p. 601; Vol. 33, p. 57; Vol. 35, p. 588; Vol. 48, p 243; Vol. 50, p. 225, Vol. 63, p. 625; Vol 68, p. 214. Also the following on allotropy are important: "On So-called Explosive Antimony," Ibid., Vol. 52, p. 129; "Amorphous Antimony and Bismuth," Vol. 61, p. 588. "On the Metastability of Metals," Ibid., Vol. 71, p. 301; "Physical Chemical Studies of Lead," Ibid., Vol. 74, p. 202. "Atomic Volumes of Allotropic Modifications at Very Low Temperatures," Ibid., Vol. 71, p. 385. "Physical Chemical Studies of Bismuth," Ibid., Vol. 85, p. 419. "Physical Chemical Studies of Cadmium, Copper and Zinc," Ibid., Vol. 87, pp. 409, 419 and 426, although the very careful electrical resistivity measurements of G. K. Burgess and Kellberg do not indicate transformation of copper.

3. Change from an amorphous into a crystalline form.

According to Beilby's theory, it appears that when tin or any other metal is rolled or otherwise deformed beyond its elastic limit, its crystalline structure is destroyed in part.[6] It is possible, therefore, by rolling or forging tin plates to extreme thinness to get almost completely amorphous metal. Such plates can show recrystallization phenomena very plainly at temperatures below the melting point[7]. Heated in a thermostat at 150 deg. C., they become dull in appearance in a few minutes, and in about one-half hour at 110 deg. C. This surface under oblique light appears to be covered with scratches and under a magnifying glass (10: 1) a net-

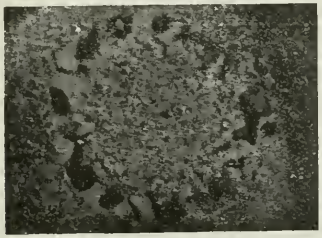

FIG. 2. RECRYSTALLIZED ANNULUS UNDER SPHERICAL DEPRESSION. × 3.8

work similar to that appearing on cast tin may be seen. This difference exists, however, that whereas the cast surface is marked with grooves separating crystalline groups, recrystallization produces a projecting mesh composed of the edges of the newly formed crystals. A study of similar cases with other metals has shown that this is not a new entity forming in the metal, but simply the merging and growth of the fractured and partly destroyed crystals.

Recrystallization of Steel

A very interesting study of the recrystallization of steel was made by Charpy[8]. He produced a depression in a piece of steel by means of a steel ball as is done in a Brinell hardness machine, and then planed this piece until the bottom of the depression was reached. The sample now had a perfectly flat and smooth appearance, but after annealing, the etched surface as viewed under the microscope had developed noticeable traces of deformation, as may be seen in Fig. 2. The large crystals on the periphery form a circle of about 10 mm. diameter, which is that of the steel ball used. Apparently, a critical shear and deformation took place near the center of this ring, which explains the more pronounced recrystallization in this place. Fig. 3 shows a part of the same circle, magnified 100 times. Crystals on the periphery are in the lower part of the picture, and the center of the circle is beyond the upper.

Stead in 1898 had shown that the grains of ferrite develop most rapidly in low carbon steel at temperatures from 650 to 750 deg. C. Charpy proved further that under the same conditions ferrite grains grow more rapidly when the piece had been cold drawn or forged. He took a piece of soft steel, cut it in two, and subjected one end to cold drawing. Then both pieces were annealed at 650 to 800 deg. C. After cooling. each piece was broken in the middle. The fracture showed that the cold-drawn piece had a much larger crystalline structure. When the drawing affected the surface layers only, then large crystals were seen only near the surface.

Microscopic study shows that the difference in structrue of such pieces of steel is only in the size of the grains of ferrite. The relative dimensions of these grains may be quite large, and in fact under favorable conditions of temperature, composition and past history the crystals may grow indefinitely until the whole piece of metal becomes one crystal[9]. This phenomenon is pronounced in the case of low-carbon steel with a certain percentage of phosphorus. The linear dimensions of grains of rolled annealed steel are ten times as large as those in annealed unrolled steel, and the volume, therefore, may be as much as 1000 times as large in

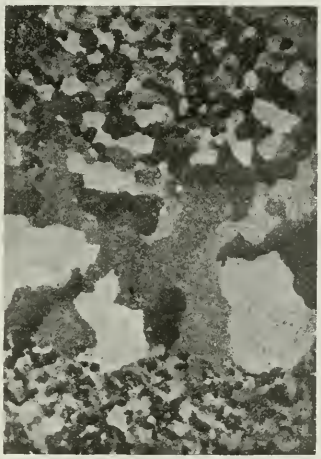

FIG. 3. RECRYSTALLIZATION UNDER SPHERICAL DEPRESSION. × 100

rolled annealed metal as compared to those in annealed unrolled steel.

Such development of crystals causes iron to be brittle. Thus, after the grains reach a certain size, the piece becomes so brittle that the work of breaking an impact specimen becomes almost zero. Charpy observed cases where steel rods, after being cold drawn, could stand considerable hammering without breaking, but after they were annealed at 650 deg. became so brittle that they broke into pieces when dropped on the floor. Every

[6]Beilby's theory of flow and resolidification in a vitreous-amorphous state postulates that layers of molecules many molecules in thickness have the mobility of the liquid state conferred upon them for a brief period; that it is the transient existence of this mobile phase which makes slip and movement among the lamellæ possible and easy and that it is the sudden resolidification of these mobile layers into a non-crystalline or vitreous condition which arrests deformation under a given deforming stress. The original surfaces of any slip are now cemented together by the more rigid material and new surfaces of slip are only developed by higher stresses. The plasticity of the crystalline state is thus gradually used up and the aggregate as a whole becomes more and more rigid. When this has reached a certain stage, further increase in stress leads not to plastic flow, but to disruption.

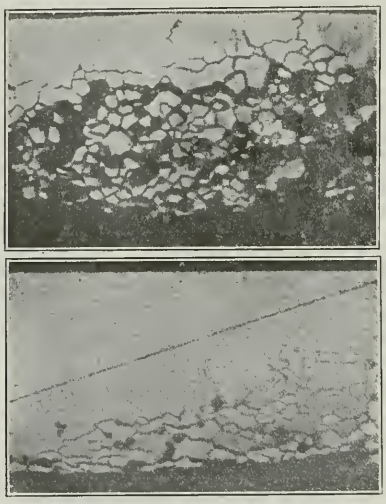
[7]Ewing and Rosenhain discovered that highly compressed lead recrystallized at all temperatures from ordinary up to the melting point.

[8]See also Sauveur's contribution to the Sixth Congress of the International Association for Testing Materials, New York, 1912, Vol. II, p. 6. Charpy, even as far back as 1893, investigated the process of recrystallization and formation of larger crystals in brass and steel under certain heat treatments.

[9]Zay Jeffries, "The Metallography of Tungsten," *Bulletin*, American Institute of Mining Engineers, No. 138, page 1037.

metallurgist can remember such facts from his practice.[10]

Cohen concluded from these considerations that rolled tin must be in an unstable (metastable) condition, and that while the change to a stable condition takes place extremely slowly at ordinary temperatures, it progresses more rapidly at higher temperatures and especially when brought in contact with the stable form. Considering recrystallization as a growth of broken crystals, we can conclude that every cause that may help the growth of crystals at ordinary temperature will also produce Hasslinger's phenomenon of infection more quickly.



FIGS. 4 AND 5. DECOMPOSITION OF SURFACE OF ALUMINIUM FLASK (AT TOP) AND ANODE (AT BOTTOM). × 50

Infection may follow a purely mechanical action: If finely polished tin is hammered obliquely at one place, this spot becomes dull and can "infect" the other tin.

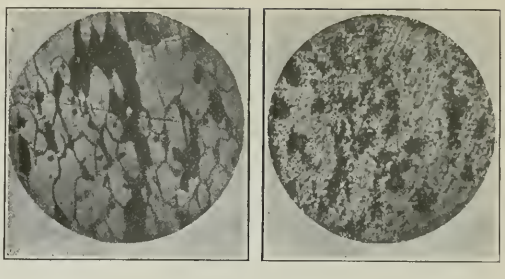
Diseases of Aluminium

The diseases of aluminium described by Ducru were studied further by Le Chatelier. He used microphotography in his work with remarkable success, as can be seen from the accompanying photographs.

Fig. 4, magnified 50 times, shows a section through the bottom of a flask which failed after a short service. The gray-black powder on the surface of this metallic utensil consists, as is plainly shown, of small grains of metal.

Fig. 5, under the same magnification, shows a similar case, except that decomposition is less pronounced. This sample was used as an anode in a solution of sodium chloride. A current of a few milliamperes was applied for a few seconds. The polishing of these samples could be done only after the grains were fixed with melted rosin, which is the dark material separating the white metallic grains. The whole structure has traces of a cellular mesh. One can also notice cracks which are beginning to isolate separate grains of metal.

[10]See Howe, "The Metallography of Steel and Cast Iron," p. 359.



FIGS. 6 AND 7. SURFACE OF ALUMINIUM ANODE AFTER ELECTROLYSIS. × 200

Fig. 6, magnified 200 diameters, shows the same sample electrolyzed for several minutes with a current of 10 milliamperes per square centimeter. Such longer treatment develops the cellular mesh over the whole surface more clearly. The black polygonal depressions indicate places where the grains were torn away. That the metal did not dissolve at these points could be noted from the condition of the electrolyte, which contained many bright metallic specks.

Fig. 7 shows the surface condition of aluminium when treated in the same way, but which has not decomposed. One can see irregular black spots where the metal was corroded by the chemical reaction, but no crystalline structure of missing crystals is evident.

According to Le Chatelier, the decomposition of aluminium may be produced by mild chemical or mechanical action, such as may take place in a utensil over a flame or when containing hot liquids.

Le Chatelier attempted to show the effect of metallic impurities on such decomposition by the following experiments: Aluminium alloys containing 1 per cent of copper, sodium or calcium, respectively, were quickly heated almost to the melting point, and later annealed a long time at 100, 218 and 300 deg. C. At 200 deg. the alloy containing calcium showed something like a mesh-work, but hardly plainly enough to allow any conclusions. With heavily forged aluminium, decomposition may take place by itself, but when heated to 450

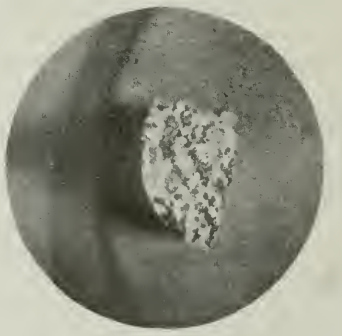


FIG. 8. FRACTURE OF CRYSTALLIZED BRASS ROD. × 1.4

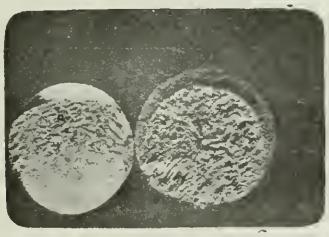
deg. C. these defects disappear. On the other hand, contact with lime water aids decomposition.

Fig. 8 shows a photograph of the break in a piece of brass rod 1¼-in. in diameter, which had been rolled and then annealed. Nothing unusual was observed by the

author about this rod until, after some months' storage, it was dropped, when it broke into pieces. The illustration shows its coarse-crystalline structure—recrystallization.

In 1909 the writer became interested in the experiments with aluminium bronze described by Carpenter and Edwards in the eighth report of the Alloys Research Committee, 1907, and produced several interesting samples in the shape of rods, cast in sand or chill molds, and afterward rolled, annealed and drawn to the required size. The bronze used consisted of 91 per cent copper and 9 per cent aluminium, and the working was all done in the cold. These rods were stored in a room where the temperature varied from about 5 to 20 deg. C. A year later a number of cracks appeared on the surface of some of these rods. Fig. 9 shows a break in a rod which did not have any surface cracks: the break has a uniform velvety appearance. The narrow white stripe shown in the photograph is due to the fact that here the fracture of the rod was considerably higher. Fig. 10 shows a similar break in a rod containing cracks, in a good portion of it between two neighboring cracks. This illustration shows a much more ragged fracture with two distinct zones, a narrow yellow crescent outside encircling the gray-white inside. Fig. 11 shows a fracture from the same faulty rod, but taken through the good portion of it where it exhibited no cracks. In appearance this fracture lies between those of Figs. 9 and 10, the yellow outer circle not being evident. The two black stripes shown on the left and right edges are the traces of the saw cut.

Many other similar cases were investigated with the same result: a large number of "season" cracks being usually accompanied by the more crystalline break, while the yellow circle sometimes covered almost the whole cross-section. Unfortunately the microphotographs



FIGS. 9 AND 10. ON LEFT—FRACTURE OF NORMAL ALUMINIUM BRONZE. ON RIGHT—OF ALUMINIUM BRONZE CONTAINING SEASON CRACKS. × 2

were not distinctive enough to draw many lines of demarcation. Also to the writer's regret it was not determined how cracks were passing—between crystals or across them. According to W. H. Bassett[11] with wrought brasses in the α phase, the cracks always pass between the crystals. H. S. Rawdon[11] in his microscopic exthe cracks pass through the beta. When the alloy is entirely in the β phase, the cracks generally pass across the crystals. H. S. Rawdon[11] in his microscope examination of samples of brass which has season-cracked in some mercury solution found that cracks were intercrystalline; in cartridge brass in which there are only the α crystals, the cracks are truly intercrystalline. In manganese bronze (60-40 brass) the cracks follow, in general, the boundary surfaces between the α and β constituents.

It has been proved beyond any doubt that cold forging and drawing may actually facilitate the decomposition of metals. These facts are characterized by Cohen as " diseases due to cold forging of metals" ("Forcierkrankheit").

Heyn's Limiting Conditions of Equilibrium

In view of the foregoing discussion, it may be stated that decomposition of cold drawn and forged metal is now firmly recognized, but we have yet no satisfactory explanation as to its true cause. Many theories have been offered, and it would be difficult to criticise them,

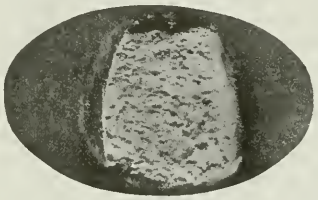


FIG. 11. FRACTURE OF CRYSTALLIZED ALUMINIUM BRONZE. × 2

since, as Heyn said, "Their usefulness may be measured only by their success in opening new scientific horizons and giving fresh impetus for further studies and experiments."

Behrens and Cohen have advanced their theory of recrystallization of metals as described above. The bearing of Beilby's amorphous theory has also been indicated.[12] A most noteworthy explanation of the observed facts, in the writer's opinion, has been offered by Heyn, who suggests that metal during drawing stores up energy, so that overstrained metal has a natural tendency to approach a stable condition which possesses the minimum amount of energy. He therefore controverts Beilby's idea that there should be considered two forms in forged material, namely, crystalline and amorphous, saying that during working the grains get longer and thinner, thus increasing the surface energy of each crystal. Consequently the total energy in the piece also increases, and the action produces an unstable condition in the metal.

Going further, one may assume that along certain surfaces of slip cold work, increased to such an extent that there remain, in consequence of the high degree of splitting up the grains, films consisting almost only of moles or groups of moles, this might be assumed to be a transition of the metal from the crystallized phase into another amorphous phase. According to Heyn, however, it would be more natural to assume that forging develops a thin layer of the same crystalline phase, in which, owing to the cold working, the potential energy is locally raised to a very high figure. In Heyn's opinion, we have to differentiate between "phase equilibria" and the equilibria which are dependent upon

[11] "The Causes and Prevention of Corrosion Cracking," by W. H. Bassett. *Proceedings*, American Society for Testing Materials, 1918, Vol. XVIII, part II, pp. 153-162. "The Use of Mercury Solutions for Predicting Season Cracking on the Brass," by Henry S. Rawdon, Ibid., pp. 189-200.

[12] *Proceedings*, International Society for Testing Materials, 6th Congress, New York, 1912, First Section, II, page 43.

the surface energy. If grains in the metal are split up or stretched by cold work the phase equilibrium remains unchanged, but the equilibrium of the size of grains and of the shape of grains is disturbed owing to the increase of the surface energy. A stable condition is attained only when each phase will have uniform crystalline grains each of such shape and form that the surface energy will be a minimum at all limiting surfaces.

From this standpoint all our metals and technical alloys are in a more or less unstable condition, depending on the size of the crystals and their elongation. The further away they are from the stable conditions, evidently, the more the tendency to approach it. Ordinarily such reversion can take place but partially, as the regroupings of the small grains with high surface energy into large equi-axed crystals of small specific energy become difficult on account of the friction offered molecular movement in the solid. This friction, of course, varies with the pressure and temperature. Consequently, for a given pressure and temperature. there exists an initial degree of equilibrium, which is materially constant.

Heyn defined this as a "limiting state," comparing it with that of a body on an inclined plane, down which it is just prevented from sliding by friction. Therefore, if any factor tends to increase the deformation of the forged metal, then, according to Heyn, this factor also increases the rapidity with which the metal approaches such "limiting state" for the given temperature, pressure and initial degree of stability.

Heyn's theory is a theory of internal strains. He, together with Bauer, even developed a method to determine the amount of such stresses, which may reach a considerable value, exceeding sometimes the ultimate strength, for instance, in forged pieces of nickel-steel, brass or delta metal. These strains disappear after proper annealing at given temperatures. According to the latest researches, they disappear even at comparatively low temperatures.

At the same time, nevertheless, all factors such as additional stresses due to mechanical forces, to irregular heating and cooling, to washing, cleaning, chemical treatment or vibrations tend to increase the decomposition.

According to P. D. Merica and R. W. Woodward,[13] "The welding or burning-in of castings or other articles will also generally produce initial stress in the cooled piece, the welded portion being in tension parallel to the surface and perpendicular to the weld. If a round bar of brass is suddenly cooled by quenching from a high temperature, the outer half of the cross-section will be left in longitudinal compression, the inner half in tension. Measurements have shown that in 1-in. round bars of naval brass and manganese bronze quenching from 450 deg. C. into water produces an average longitudinal, initial compressive stress over the outer half of the cross-section of 14,500 lb. per sq.in."

Investigating the cause of the frequent splitting of the thin steel pipes used in evaporating and precipitating potassium and sodium carbonates, Stromeyer[14] noticed that these cracks appeared only in places where the pipes were subjected to tensile forces. He then prepared specimens, each of two rings, of which the outer one was forced under pressure over the inner one so that the inner one was under compression, with the outer one under tension. These double rings were placed in a solution of sodium carbonate under the same conditions as obtained in the commercial apparatus, and he found that the outside ring cracked, while the inside remained intact. Unstressed rings also remained unchanged.

Heyn cites these interesting experiments conducted by Stromeyer, and points out that some particles in forged metal may be under unbalanced tension as compared with the tension of other particles. Similar strains exist within certain limits in metals subjected to cold shearing. It is interesting to note that somewhat similar stresses were described and explained by Professor D. Tchernoff in his report to the Imperial Russian Technical Society in 1884. He studied the stresses which appear after cold punching or shearing of steel plates and noted that they spread in waves, increasing the elastic limit of the material in the crests of the waves. This phenomenon is known as the "Lüders-Tchernoff lines." Some years later (1895) it was described also by Captain Hartmann. It must be noted, however, that Tchernoff's lines were first observed and described in 1860 by Lüders, who gave them a different explanation[15].

New Process for the Manufacture of Sulphonic Acids

The Department of Agriculture announces that the Color Laboratory of the Bureau of Chemistry, Department of Agriculture, has developed on a laboratory scale a new process for the manufacture of certain sulphonic acids. This process, as carried out in the laboratories, appears so promising that it is thought that some manufacturers of chemicals and dyestuffs in this country may be able to supply their demands for these and other valuable compounds by this process, provided the process can be reproduced upon a technical scale so as to obtain results commensurate with the laboratory investigations. The process refers particularly to the sulphonation in the vapor phase of benzene, naphthalene and other hydrocarbons.

With a view to helping the chemical industry of this country, the Department of Agriculture announces that it is ready to assist manufacturers who wish to produce these compounds. The expenses of the technical installation and of the labor and materials necessary will of necessity be borne by the firm, individual or corporation wishing to manufacture the products. The chemists of the Color Laboratory will assist with expert advice, etc. The Department reserves the right to publish all the data obtained from the technical experiments. This offer of assistance will not be held open by the Department for an indefinite period.

Temperature Uniformity in an Electric Furnace*

A Method of Manufacturing Laboratory Electric Furnaces Producing a Uniform Temperature From End to End of Core—Three Independent Heaters in Addition to End Plugs—Alternate Layers of Insulating and Conducting Materials to Distribute Heat

By JOHN B. FERGUSON

THE problem of temperature uniformity in an electric furnace is intimately connected with almost all investigation carried on at high temperatures. For this reason it has generally been considered as a part of a larger problem and has been solved to the extent demanded by the requirements of the work at hand. In the present paper the writer wishes to discuss the conditions essential for a proper control of the temperature distribution, and the previous attempts that have been made to attain these conditions; and to describe in detail a type of horizontal furnace which he has found suitable for investigations requiring a uniform temperature over the range from 620 to 1190 deg.

General Discussion

The maintenance of a region of uniform temperature in an electric furnace requires that full compensation be made for the heat losses at all points within this region, and the ease with which such a compensation may be obtained is an inverse function of the magnitude of these heat losses. This is not, however, the only factor to be considered in determining the insulation required by any given furnace. If a uniform temperature is to be obtained this insulation must be thick enough to render negligible the effect of non-uniformity in the temperature of the furnace surroundings, and if, further, a constant uniform temperature is to be obtained the insulation must also be of such thickness that fluctuation in this external temperature with time will be without effect. In the former case alternate thin layers of a good conductor and a good insulator may be used to advantage to replace thick layers of a slightly poorer insulator, giving the same uniformity of heat losses but with much reduced lag effects.

The heat losses are never uniformly distributed in a furnace, and the heat supply must likewise be non-uniformly distributed. If the heat losses are of different magnitudes but all similarly dependent on the furnace temperature (an unusual case) a non-uniform heater could be constructed which would afford a compensation over a range of temperatures; but if these losses are not similarly dependent on the furnace temperature (the usual case) then such a non-uniform heater would provide a compensation at one temperature only. In this latter case, if a compensation is desired over a range of temperatures, the single non-uniform heater must be replaced by as great a number of independent heaters as there are indpendent heat losses.

The ordinary electric furnace in which a column of air is heated is the best known example of a region with non-uniform heat losses and is the type the writer wishes particularly to consider. In such an air column, provided convection is eliminated, there will always be a short region having a fairly uniform temperature. The length of this uniform temperature region will be dependent upon the length of the furnace, and for some work a furnace sufficiently long to provide a suitable region of uniform temperature can be used without further attention to end conditions. But the usual problem confronting an investigator is to increase the length of this region without increasing the length of the furnace. The introduction of insulating plugs or baffle plates will cut down the end losses by conduction and radiation and will give a result similar to that obtained by lengthening the furnace. For this purpose a plug of good insulating material is much less efficient than a composite plug made up of good and poor conducting layers, the first of the former being on the inside of the plug next the region to be uniformly heated. Such a plug has two functions: (1) to reduce the end losses by insulating the region, (2) to distribute the heat losses and also the heat supply uniformly across the plug and thus take full advantage of the heating effect of the ends of the heater. This latter precaution is particularly important in furnaces of large diameter.

In many cases the region to be heated uniformly is such a large portion of the whole air column that even composite plugs are inadequate and in this case the simple uniform heater has to be discarded. A specially wound heater designed to give an increased heat supply at the furnace ends will increase the length of the region of uniform temperature and will yield a maximum length at one particular temperature, since with the materials at our disposal the average furnace must be so constructed that the relation of the heat losses to the furnace temperature varies. The use of a furnace of this type is naturally limited, since it is difficult to design a heater that will give the maximum length to the region of uniformity at a predetermined temperature. Special and separate end heaters independent of the main heater offer the most practicable solution, as they enable one to obtain equally good compensation over a range of temperatures.

In designing such a furnace the thickness of the layers of good and poor conducting materials employed will depend on the conditions under which the furnace is to be used and the degree of uniformity required. In general a horizontal furnace gives a better temperature distribution than a vertical furnace of the same dimensions. Two reasons may be given for this: (1) The convection currents in the air column of the vertical furnace are more active and may be considerable if the furnace is not gas tight; and (2) the temperature

*Republished from *Physical Review*, Vol. XII, No. 1.

distribution over the outside of the vertical furnace is much less uniform than in the case of the horizontal furnace. The horizontal furnace has therefore been much more frequently used and was the type employed by the writer.

Almost all investigators in the field of high temperature have been obliged to consider the problem of temperature uniformity. In this paper it is obviously impossible to present all the results that have been obtained and the writer has chosen to present only the work which best illustrates the points he desires to emphasize. In fairness to those quoted the reader should remember that most of them were interested in the development of a furnace suitable for their particular need and in that alone.

Previous Work

Among the earliest investigators to touch upon this problem were Holborn and Day,[1] who in 1899 experimented with both uniform and non-uniform heating coils. They found that the latter gave the better temperature distribution but with an optimum uniformity for a short range of temperature.

A somewhat more complicated furnace was used by Waidner and Burgess[2]. It consisted of two concentric furnaces, the outer having a long heater with crowded end windings while the inner was shorter and uniformly wound. In such an arrangement, the end and center heat supplies are only partially independent of each other and so the compensation is still a function of the temperature, although not as dependent on it as in the case of the single non-uniform coil. These conclusions are entirely borne out by their results.

In 1908 Day and Clement,[3] confronted with the same problem that had confronted Holborn and Day in 1899, were able with a new furnace to obtain along their gas-thermometer bulb a temperature distribution which did not vary over 1 deg. up to 1200 deg. This they did by means of independent auxiliary end heaters which, like the main heating coil, were wound (one in each end) on the inside of the furnace tube and were separated from the main coil by a layer of refractory magnesite cement.

Two slightly different types of furnace were used by Day and Sosman[4] in continuing the work of Day and Clement in 1910. Both had baffle plates in the unused portions of the air column which cut down the end losses by radiation. These end radiation losses, which seem to have been overlooked by all the previous investigators, were found to be of considerable magnitude. The furnaces differed only in the form of the heaters. In the first, the main heater was slightly crowded at the ends and inside wound, while the end coils were similar to those used by Day and Clement. In the second, the heating coil was divided into three units subject to independent control, and was wound on the outside of a thick tube of good conducting material. This second furnace yielded the better temperature distribution but could not be used at the highest temperatures.

The three-heater principle first used by Day and Clement was also employed by Gray,[5] who desired the greatest uniformity attainable. Instead of separating his good conducting baffles by air as Day and Sosman had previously done, he used a layer of a good insulating material. This type of plug, though very similar in principle to the plug used by Day and Sosman, is probably better, since it is a better longitudinal insulator. The fact that metal baffle plates separated by thin layers of air form, in effect, a composite plug conducting transversely and insulating longitudinally apparently did not occur to Gray, who independently later developed the idea. His first furnace, in addition to such plugs, contained thick-walled iron tubes and was heated by three independent heaters; the main heater was of basket weave; the other two were situated in the outer portion of the plugs. Evidence of severe local heatings led him to rebuild the furnace with two concentric heaters of basket weave and larger end coils which now were placed outside of the plugs and covered a considerable portion of the furnace ends.

Gray did not fully appreciate the value of the independent heater idea[6] and attributed his success mainly to other causes. His description implies that such plugs as are described above will enable one to use a furnace with crowded windings over a range of temperature. This is generally true, for if the windings

[6]In his discussion of this subject, Gray apparently overlooked the various investigations in connection with high-temperature thermometry, for he says: "Previous experimenters have tried to secure uniformity of temperature in an electrically heated air column by using the central portion of a long tube and by crowding the windings near the ends or other places where the heat was lost most rapidly," whereas several of the investigators referred to had already used independent end heaters.

are crowded so as only partially to compensate over the range of temperatures at which the investigator wishes to work the additional compensation may be obtained from the end heaters and a good temperature distribution will result. It will not be a convenient furnace to work with, however, as will be discussed later. But if the furnace is so wound that at any temperature within the range of temperatures considered a perfect compensation is made without the end coils, then at higher temperatures there will be under-compensation and at lower temperatures over-

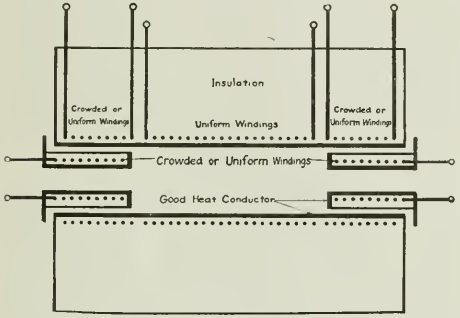

FIG. 2. IDEAL SECTION OF CYLINDRICAL FURNACE WITH INDEPENDENT END HEATERS AND PLUGS

compensation by the crowded ends. Obviously, if there is over-compensation a plug by means of which the supply of heat at the ends can only be kept constant or increased offers no possibility of a solution. The basket weave would seem to have been a detriment rather than an aid, since a single main heater of that type was insufficient and two were necessary to avoid severe local heatings.

The form of the plugs is not as important as would appear from Gray's experiments. The main requisite is the separation of the heaters from the region to be heated by sufficient material to smooth out any local

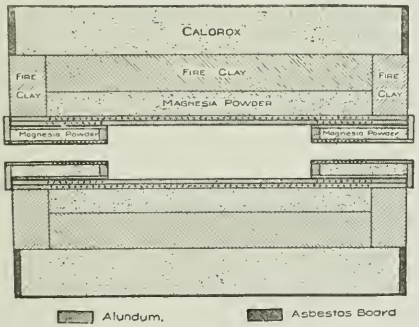

FIG. 3. CROSS-SECTION OF CYLINDRICAL FURNACE WITH END HEATERS AND PLUGS, SHOWING DETAILS OF CONSTRUCTION

heating effects. Just how much latitude there may be in the designing of plugs, end coils, etc., may be gathered from the work of Allen and Lombard[7] and also that of the writer. The furnace of Allen and Lombard had flat end coils that did not cover the plugs, and also solid asbestos caps, while the main heater was a single coil wound on a helically grooved alundum tube with walls 0.5 mm. thick. With this furnace a uniformity equal to that obtained by Gray at approximately the same temperature was obtained. In Fig. 1 curves representing some of the work referred to are given.

[7] *Am. J. Sci.*, 43, 175, 1917.

Experiments

The actual design of any furnace is dependent on the purposes for which it is intended and the materials and facilities the experimenter has at hand. It is therefore doubtful whether any special design will have a very general application.

Nevertheless a description of a furnace may furnish the prospective designer with much useful information, and for this reason a description of a 45-cm. furnace capable of uniformly heating a region 6 cm. in diameter and 10 to 12 cm. long at temperatures ranging from 1000 to 1200 deg., and maintaining this uniform temperature constant for long periods of time, will be given. In the development of this furnace a number of types were tested out, and of these a few proved satisfactory. The final changes were made with the intention of

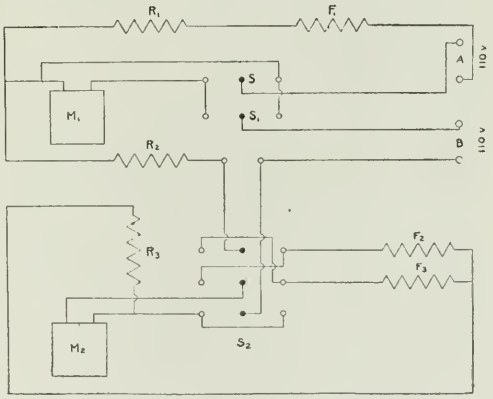

FIG. 4. A CONVENIENT PLAN OF ELECTRICAL CONNECTIONS FOR THE FURNACE WITH INDEPENDENT END COILS

simplifying the construction and regulation rather than of improving the temperature uniformity, since the latter could be obtained in several of the furnaces.

The final design is shown diagrammatically in Fig. 2. The end coils may be either crowded or uniformly wound, but the main central heater must be uniformly wound. Equally good compensation will result if the central heater has slightly crowded winding, but the resulting furnace is not as convenient to use over small ranges of temperature. For example, with a uniformly wound heater at a given temperature changes of ten degrees or so in the furnace temperature can be obtained by regulation of the central heater current without disturbing the compensation much, whereas in a central heater with crowded end windings, the same change in the current would have necessitated considerable adjustment of the end coil current. The end coils should be more closely wound than the center, thus increasing their resistance and lessening the danger of severe local heatings. The heaters are shown as independent units. This

renders possible a variety of connections. In some of the writer's work the tube to be heated was very short and it was therefore desirable to heat the ends as little as possible. Satisfactory results were obtained by running the plug coils in series with the center coil and compensating by means of the end coils. In practically no experiments was a good compensation obtained by running the two end coils in series, as one end invariably required more current than the other.

The actual furnace is shown in Fig. 3. The large amount of insulation was necessary in order that a

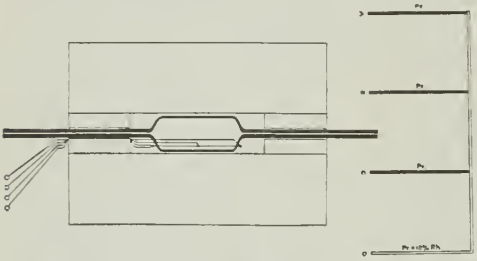

FIG. 5. SECTION OF FURNACE WITH GAS BULB AND COMPOUND THERMO-ELEMENT

FIG. 6. COMPOUND THERMO-ELEMENT

constant temperature might be maintained over long periods of time. The construction of the heater and plugs may be thus described:

Heater.—Two helically grooved alundum tubes were selected of such a size that the smaller readily slipped inside the larger and was of 6 cm. inside diameter. A coil of 0.8-mm. platinum wire was wound on each end of the smaller tube for a distance of 10 cm. from the ends, and the whole was covered with alundum cement and baked. When hard the excess alundum was removed until this tube would just slide into the larger tube. A hole was bored through the large tube at each end at the inner edge of the end coils, and the inner wire ends, which had purposely been left long, were brought out through these holes. The smaller tube was then slid into the larger and these ends drawn tightly through and then wound back on the outer tube to its ends. The central portion of the outer tube was then separately wound with similar wire and the whole covered with alundum cement and baked.[8] This peculiar method of winding was found to be necessary because alundum cement is not as good an electrical insulator as many suppose. Two furnaces, constructed with uniform main heaters extending the full length of the tube and with end heaters wound around the main heater and insulated from it by 0.5 cm. of alundum cement, did not even survive their trial heats, as the current arced from the main to the end coils, burning them out.

Plugs.—The principal details may be observed in Fig. 3. The inner and outer alundum tubes were cemented to an alundum disc with water glass. The space between the tubes was filled with freshly ignited magnesia powder to within 1 cm. of the end and this magnesia held in place by means of a paper washer. The remainder of the space was filled with alundum cement and the whole baked. In order to insure a good tight fit the outer alundum tube was usually coated with alundum cement, and when this had hardened the plug was filed down until it would just slide into the furnace. The inside of the outer edge of each alundum disc was covered with asbestos wool stuck on with water glass, thus insuring a tight fit when the plug was pushed home and eliminating any radiation losses through the crevices.

The use of alundum with burnt magnesia and fireclay in all the hot portions of the furnace assures consistent results from the furnace day after day even at quite high temperatures with practically the same current. The calorox which forms the outer insulating layer is unsuitable at temperatures as high as 1000 deg. The outer shell is of sheet iron, painted with aluminium paint. We find that this paint reduces the total heat losses by reducing the radiation, thereby increasing the temperature of the shell and decreasing the temperature gradient across the insulation.

Electrical Connections.—As has already been stated, the exact method of making electrical connections will depend on the particular use that is to be made of the furnace. Three separate electrical controls will be almost always essential, although the current required by the end heaters will usually be very nearly of the same magnitude. The writer was able to take advantage of this fact in developing a set-up whereby all the adjustments could be obtained from two main circuits with

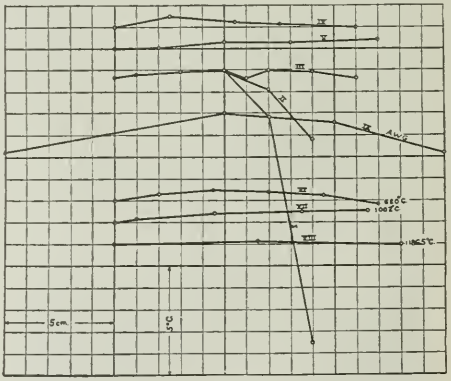

FIG. 7. TEMPERATURE UNIFORMITY

considerable saving both of current and the operator's time.

A diagram of these connections is shown in Fig. 4. *A* and *B* are the two main circuits. In *A* the current always flows through the furnace coil F_1 and the variable resistance R_1 and can be made to pass through the ammeter M_1 by means of the switch S. In *B* the current has two routes, depending on the way the switch S_2 is

[8] A smooth (1-cm. thick) alundum tube upon which the end coils might have been more closely wound than the center would have been easier to handle, but unfortunately was not available.

thrown. As in *A*, the current always passes through a variable resistance R_2 and at will may be made to pass through M_1 by means of switch S_1. The function of the three-way switch S_2 is to place the variable high resistance R_3 in parallel and the ammeter M_2 in series with one of the furnace coils, either F_2 or F_3, at will. If the switch S_1 is thrown to the left and the switch S_2 to the right the current follows the route S_1, M_1, R_2, F_2, R_3 in parallel with F_3 and M_2, and back. The upper ammeter shows the total current, i.e., current through F_2, and the lower the current through F_3. With this arrangement the current through F_3 will always be equal to or less than the current through F_2 but by reversing the switch S_2 the position of these furnace resistances is reversed and so all the required adjustments can be made. If nearly the same amount is required through both F_2 and F_3 the amount wasted in R_2 will be very small.

Temperature Measurements.—In the earlier work a single platinum-platinrhodium thermoelement tube was used. It was mounted in a Marquardt porcelain thermoelement tube having two small holes bored in the closed end, through which the wires passed; the junction was bare and bent so that it would come in contact with the gas balloon which was to be maintained at constant uniform temperature. The thermoelement tube could be inserted or withdrawn from the furnace and the measurements were always made when the tube was about to be withdrawn, since on inserting the tube the uniformity was somewhat disturbed. When the local heatings were found negligible this thermoelement was replaced by a compound element of the form shown in Fig.6, by means of which direct or differential temperature measurements could be obtained at any one of three points with but four leads. Fig. 5 shows one of these later set-ups. At 1000 deg. no trouble with leakage was experienced, but at 1200 deg. it caused considerable trouble, especially whenever any part of the element came in contact with the hot alundum

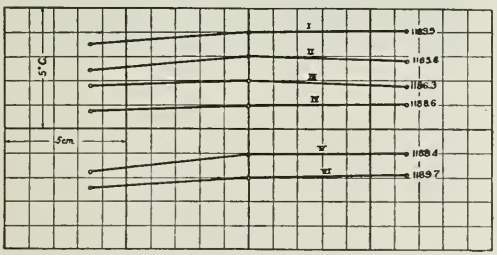

FIG. 8. TEMPERATURE UNIFORMITY. THESE CURVES REPRESENT THE FURNACE DISTRIBUTION OBTAINED DURING A SERIES OF EXPERIMENTS AT APPROXIMATELY 1190 DEG.

furnace tube, and necessitated careful shielding in the furnace itself. This was obtained by placing in the furnace a sleeve of thin platinum foil connected to the outer shield, and carefully insulating the same from the element itself by enclosing most of the latter in Marquardt porcelain. The measurements were made by means of the usual potentiometer set-up.[9]

[9] W. P. White, "Potentiometer Insulation, Especially for High Temperatures and Thermoelectric Work," *Physical Review*, XXV, 334-352, 1907.

In most of the investigations no greater uniformity than ±0.5 deg. was necessary and no attempt was made to improve on this. The apparatus is undoubtedly capable of producing a uniformity of ±0.2 deg., the limit set by local heatings, provided the experimenter is willing to take the trouble with the current adjustments.

Figs. 7, 8 and 9 are curves representing the results. Unfortunately furnace V was not used with the same set-up on different days, so that no comparison can be

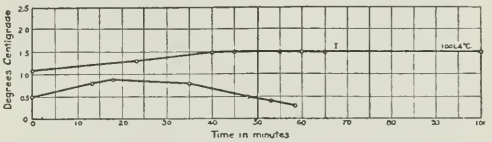

FIG. 9. TEMPERATURE CONSTANCY

Curve I: The fluctuations in the furnace temperature with time in part of a four and a half run with furnace IV at 1001.4 deg. Curve II: The fluctuations in the furnace temperature with time in a run with furnace V at approximately 1190 deg.

made of its performance on different days with the same current. At 1190 deg. with a porcelain tube 3 cm. in diameter at the center and somewhat smaller ends the current required on 110-volt circuit to give a uniformity of ±0.5 deg. was: Left, 5.65; center, 5.50; right, 5.55 amp. Furnace IV was constructed of exactly the same material as furnace V although of different shape, and one may with reasonable certainty infer that if furnace IV would reproduce a given temperature uniformity furnace V would also. Table I gives the results obtained in four separate runs with furnace IV.

TABLE I.—ENERGY REQUIRED UNDER DIFFERENT CONDITIONS OF END RADIATION

Set Up	Date	Left Coil, Amp.	Center Coil	Right Coil	Temperature Distribution
Porcelain tube *A*..	Dec. 7, 1915	3.35	5.1	3.30	1001.0 ± 0.5°
	Jan. 6, 1916	3.35	5.1	3.35	1000.4 ± 0.5°
Transparent silica tube *B*.....	Feb. 21, 1916	4.04	4.95	4.06	1000.0 ± 1.0°
	Mch. 15, 1916	4.05	5.02	4.06	999.5 ± 1.0°

Particular attention is directed to the great difference in the current required by the end coils in the two different set-ups. The heat lost by radiation through a transparent silica glass capillary tube of 1-cm. outer diameter and 1-mm. bore necessitated the increasing of the current in the end coils from 3.35 to 4.06, an actual increase of 0.71 amp., or 21 per cent, and confirmed the observation of Day and Sosman on the magnitude of the end radiation heat losses.

Summary

The production of temperature uniformity in an electrically heated air column can best be accomplished by means of three independent heaters in addition to end plugs. The entire region to be heated should be surrounded by a layer of conducting material sufficient to smooth out any local heatings, and the whole furnace should be so insulated that the effect of non-uniformity in the temperature of the furnace surroundings is rendered negligible. The use of alternate layers of good and poor conductors will reduce the total amount of insulation necessary, but if constancy of temperature as well as uniformity is desired the insulation must be of such thickness as to eliminate the effect of temperature fluctuations in the furnace surroundings during the period the furnace is in use. This type of

furnace has the advantage that it may be converted into a simpler type if less uniformity is adequate by merely changing the mode of connecting the heaters.

A furnace embodying these principles is described in detail. This furnace yielded a temperature uniformity of ±0.5 deg. at temperatures ranging from 620 to 1190 deg.. and at 1000 and 1190 deg. a temperature constancy of ±0.25 deg. for periods of time exceeding an hour. With greater care in adjustment a uniformity of 0.2 deg. should be possible, and without doubt the furnace could be run at much higher temperatures without great loss in efficiency. The furnace is economical of current and will reproduce practically the same conditions on different days with the same amount of current provided the temperatures are below that at which magnesia powder begins to pack.

Some results indicative of the behavior of several different furnaces and set-ups are presented for their comparative value and also with the view of indicating the magnitude of some of the effects obtained.

Geophysical Laboratory, Carnegie Institution of Washington, Washington, D. C.

Exports of Glycerine in 1918

The Department of Commerce, through the Division of Statistics, gives out the following figures of the exports of glycerine to all countries during the calendar year 1918:

Countries	Lb.	Value	Countries	Lb.	Value
France	3,100	$2,530	Dominican Republic	1,476	$1,145
Italy	12,133,339	6,163,011	Argentina	512	354
Norway	50	35	Bolivia	2,515	2,001
Portugal	100	72	Brazil	1,493	998
Spain	56	38	Chile	10,121	7,134
England	6,575,725	3,728,718	Colombia	4,026	3,115
Scotland	246,795	144,354	Ecuador	1,552	968
Ireland	224	161	British Guiana	2,495	1,859
Bermuda	50	38	Dutch Guiana	120	101
British Honduras	46	41	Paraguay	20	18
Canada	1,851,937	1,107,249	Peru	2,886	2,309
Costa Rica	403	289	Uruguay	1,050	723
Gautemala	1,209	930	Venezuela	5,412	3,583
Honduras	441	376	China	7,667	5,562
Nicaragua	677	511	Chosen	87	24
Panama	3,653	2,392	British India	1,480	1,007
Salvador	954	718	Dutch East Indies	105	73
Mexico	13,331	10,645	Hongkong	200	143

Total	48,745	$4,308,518	3,117	$264,096	$2,547

Improved Treatment of Burns

THE war that has so recently closed has been no exception to those of the past in that all the medical and surgical arts were most intensively developed. Notable among the successes was the treatment of burns by Barthe de Sandfordt, who had spent sixteen years in trying to overcome the prejudices of the medical fraternity to his closed wax seal treatment. It was only when the hospital at Issy les Moulineaux was filled with many patients suffering with burns that it was considered advisable to depart from the usual practice and prove out this method experimentally.

The paraffine wax composition, called ambrine by de Sandfordt, is sprayed on the wound at 140-150 deg. F. and then absorbent cotton is plied on alternately with wax layers. The aggregate of wax and cotton seals the wound and thermally insulates it as well, the temperature of the ambrine at the skin being found to be 106 deg. F. for several hours after each 24-hr. dressing. This method is actually a case of incubation, wherein the flesh and skin cells propagate themselves in a most remarkable manner. However, all infection and bacteria must be excluded if present by some such means as Dakin's hypochlorite solution with Carrel's technique, or the incubation of flesh and skin cell destroying bacteria will result, with the balance sheet showing nothing but loss. Fresh burns, being sterile, of course are ideal for the ambrine treatment, and it has been with them that the most marvelous cures have been made.

The warm dressing has an additional virtue in that it draws the fire instantly from the wound and allows the patient to become normal. Dr. R. C. Casselberry treated the 75 employees burned at the Essington, Penn., powder explosion and reported the advantages of the embrine treatment as:

Relief from pain to a great degree.
Cleaner and more comfortable.
Fewer scars and contractions.
Skin grafting rare.
More rapid healing.
Superior in every way to other methods commonly used.

The Army surgeons have had such marvelous success with ambrine in treating all sorts of burns that it became necessary to establish the Ambrine Laboratories, 347 Madison Ave., New York City, to supply the demand. All manufacturing plants dealing with hot materials and having frequent burn accidents will do well to become acquainted with the results reported in the current medical literature.[1]

British Import Restrictions

On March 4, the War Trade Board announced that individual import licenses were required for the importation of dyestuffs into the United Kingdom. The list included all synthetic dyes, intermediates and color lakes, in paste, powder, solution, or any other form.

Later it was announced that, for the present, general licenses will be granted for the importation of products covered by the prohibition if they are of bona fide French, American or Swiss origin. These licenses will be modified as domestic manufacture develops, so that only essential colors and intermediates will be permitted to enter the country.

Production of Hydrogen and Water Glass by the Silicol Process

SEVERAL years ago George F. Jaubert described[1] the military methods in use at that time for the production of hydrogen, among which the reduction of water by silicon was of chief importance for military purposes such as for dirigibles, etc. Siemens and Schuckert were the original investigators and worked out a process[2] for the production of hydrogen from the reaction:

$$Si + 2NaOH + H_2O = Na_2SiO_3 + 2H_2$$

Initially steam was employed, but later it was found that the heat of solution of the caustic was sufficient

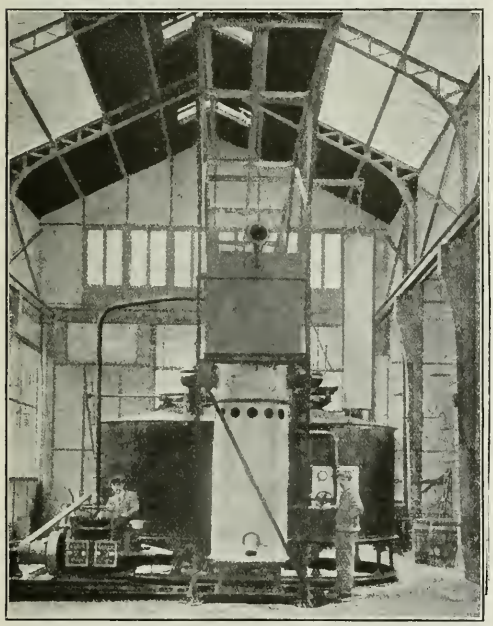

FIG. 1. GENERAL VIEW OF THE BRITISH ADMIRALTY HYDROGEN PLANT

to start the reaction and that it would maintain itself thereafter. The process was a chemical success, but due to the high price of silicon, was not economical.

In order to reduce the costs of the pure silicon, Captain H. Lelarge substituted silicon alloys in the process, successfully operating the reaction with a silicon iron containing as little as 18 per cent silicon. However, the 50 to 80 per cent ferrosilicons were much preferable. *Engineering* in its Jan. 24 issue gives a description of one of the British Admiralty hydrogen gas plants, the production of which in peace times may be utilized in oil refining by the water-glass method and hardening by hydrogenation, offering an outlet for both the sodium silicate and the hydrogen at abnormally low costs.

The plant operates the silicol process, which consists

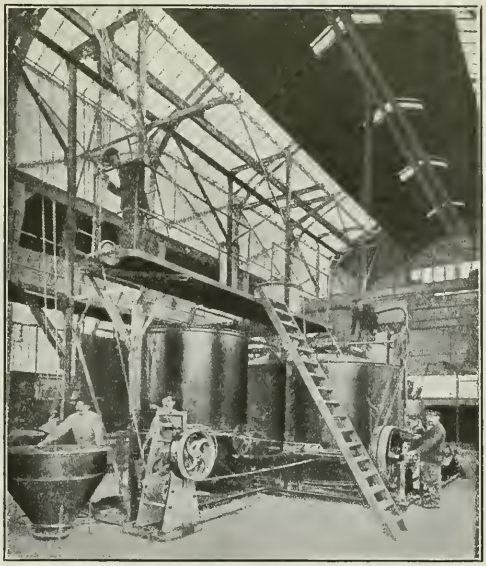

FIG. 2. PUTTING SODA IN THE HOPPER

in the decomposition of silicon alloys obtained in the electric furnace, such as ferro- or mangano-silicon, or even silicospiegel, by a concentrated solution of caustic soda (35 per cent to 40 per cent of NaOH). In the silicol process, the silicon alloys are made to act on a caustic alkali solution having a high boiling-point, the object being to retain in the solution itself all the heat

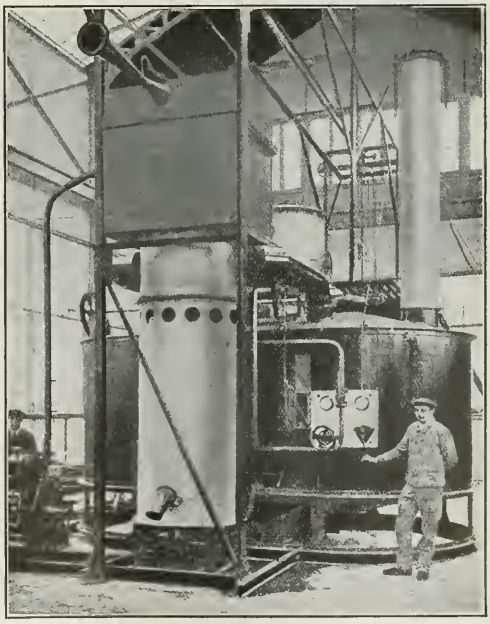

FIG. 3. WATER GAGE AND VALVE OPERATING GEAR

generated by the reaction in the combination of the silicon with the alkali, thus doing away with all outside heating.

The installation contains a vat provided with a stirring device for preparing the caustic soda solution. The lower part of the vat is fitted with a pipe provided with a valve and ending in a gas generator; the latter is fitted with a "planetary stirrer," and has at its top part a receiver containing the silicon alloy. The receiver has a hopper-shaped base in which acts a distributor worked by a crank.

The plant operates as follows. Soda in lumps, in pieces of cylindrical shape or in slabs, is put in a vat, to the extent of one and a half times or double the weight of soda to that of water; the stirring device is started running and the dissolution of the soda takes place, the heat thereby evolved being sufficient to raise the temperature to about 60 deg. or 80 deg. C. The solution is then led into the gas generator, which it should reach at a temperature sufficient to start the reaction on contact with the silicon alloy. The "planetary stirrer" causes the silicon alloy powder falling from the hopper-shaped base of the receiver to come into intimate contact with the caustic soda solution, and prevents it from accumulating in the center of the generator. The hydrogen gas, which is evolved at a high temperature, flows into a scrubber-condenser, where it loses the water vapor it contains and is cooled at the same time. The hydrogen gas then flows out through a pipe for utilization. Fig. 2 shows the soda being put into the hopper shown to the left of the view, the hopper being then raised and placed in the vat. Fig. 3 shows the water gage; Fig. 4 the starting of the water pump, and Fig. 5 the turning of silicospiegel preparatory to its utilization in the silicol process.

The water used for cooling the gas in the scrubber-condenser, which leaves this at a temperature close upon

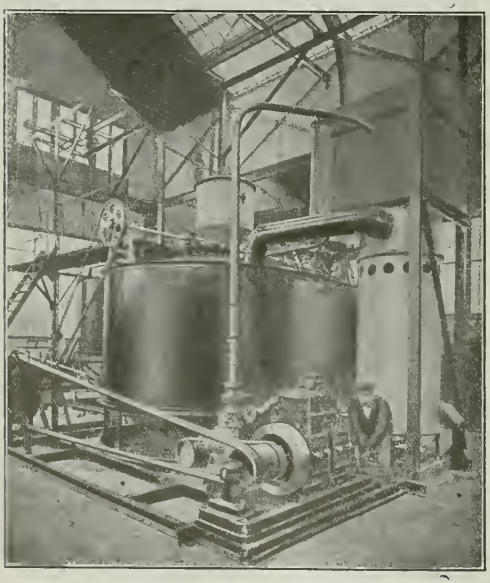

FIG. 4. STARTING THE WATER SUPPLY PUMP

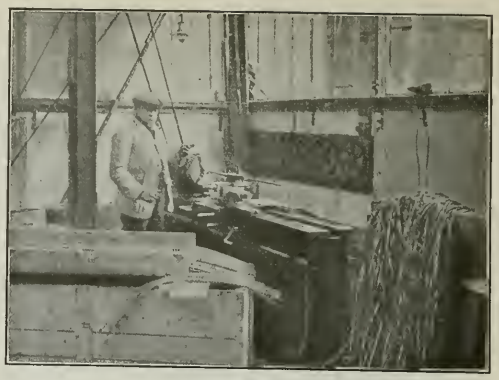

FIG. 5. TURNING THE SILICOSPIEGEL FOR USE IN THE PLANT

boiling-point, is recovered, and is utilized in the vat or in the gas generator as needed.

The advantages of the silicol process lie in the use of a silicon alloy in which the cost of the unit of silicon is a low one compared with that of the industrially pure silicon hitherto used for the same purpose, this leading to a great reduction in the cost price of the hydrogen gas. In installations where a weak solution of caustic soda is used, a neutral silicate of soda is formed, while when working, as is the case in the plant we illustrate, with a concentrated solution, an acid silicate poorer in soda is obtained; this leads to a saving in caustic soda and allows the obtaining of non-caustic residues which can be utilized for dyeing and bleaching.

The water-gage can be suitably connected to the powdered silicon alloy distributor so as to cause the delivery of the alloy powder to vary automatically with the consumption. The alloys which have given good results are the various grades of ferrosilicon, manganosilicon and silicospiegel. One single silicol plant of the type referred to can fill in half a day the largest type of dirigible, producing at the rate of 60,000 cu.ft. per hour.

As the silicol process was considered initially to be limited to military work, no patents were taken out in the United States by the inventors. The time limit has now expired and there is no doubt that full advantage of this economical process will be taken by many oil refiners. Hydrogen has been found to be a most satisfactory sweeping gas for deodorizing purposes, not having the tendency to hydrolyze the oil and thus giving a sweeter product than can be obtained with superheated steam. In producing neutral oil with water glass, the foots separate readily and give an excellent soap powder stock, sufficient bicarbonate being added to destroy the excess water glass content and produce a fine silica grain filler.

The process often may prove economical in plants where only the hydrogen is consumed and the water glass sold in the vicinity. By recovering a larger part of the caustic soda with a mercury cell, the process might be made cyclic. The diminished alkali content in the water glass would be advantageous for most purposes, especially in oil refining.

Fuel Economy in the Boiler House—III*

A Description of the German Types of CO_2 Recorders Which Depend on Measurements of the Physical Properties of Flue Gases—Thermoscope, Arndt's Gas Balance, Krell, Telezometer, Haber-Loewe Refractometer Instruments—Checking Recorders With Orsat Apparatus

By J. B. C. KERSHAW

ALTHOUGH the CO_2 thermoscope is neither continuous nor recording in its action, it may be briefly mentioned here, for the principle upon which it is based is capable of application to a recording type of apparatus. The instrument is shown in Fig. 1, and depends for its action upon the heat generated when carbon dioxide gas is brought into contact with dry caustic soda, the chemical reaction which ensues leading to a generation of heat which is proportional to the percentage of CO_2 contained in the gas sample. The instrument consists of a cylinder fitted with a plunger, by means of which a definite and measured volume of the gas from the flue is drawn into the cylinder. This gas is then forced by the downward movement of the plunger through a small cartridge containing dry pulverized caustic soda. A thermometer is placed on the instrument with its bulb so constructed that it forms a jacket to the caustic soda cartridge, and therefore records accurately the amount of heat generated. A movable scale is attached to the inside of a slot in the cylinder, and by the aid of this the percentage of CO_2 is read off directly.

The Arndt Gas Balance or "Econometer"

In Fig. 2 is illustrated the Arndt gas balance or "econometer," which, as its name implies, is designed for the purpose of weighing the waste gases which pass to the chimney, the record obtained being a continuous and not an intermittent one. If placed in a conspicuous position in the boiler house, the variations in the weight, and therefore in the percentage of CO_2 in the gases, can thus be easily seen and noted. The action of the Arndt gas balance is based upon the known fact that carbonic acid gas is one and a half times heavier than air, the respective weights of one liter being 1.97 and 1.29 grams. An increasing percentage of CO_2 in the waste gases will therefore be indicated by an increase in their density, and if there be no moisture present, the variations in density may be employed as index of the CO_2 contents of the gases.

The method of operation of the instrument is as follows: The gases are drawn continually from the flue at *E*, by means of the steam jet *D*. On their way through the apparatus they pass first through the filter *A* and drying tubes *B*, and then through the weighing bulb *C*. The scale of the balance is graduated so that the percentage of CO_2 can be read off directly, and if it is desired the instrument can also be provided with a recording attachment of the usual type, so that a permanent record of the variations can be obtained.

*The previous articles appeared in Chemical & Metallurgical Engineering, Vol. 20, No. 4, Feb. 15, 1919, and Vol. 20, No. 5, March 1, 1919.

The Krell CO_2 Recorder

Fig. 3 shows the Krell CO_2 recorder, which is closely allied to the Arndt gas balance in principle, although in this case a very delicate differential pressure gage is employed to determine the difference in weight of measured volumes of the flue gas and air. This gage is attached to two columns of equal height, the one containing air and the other the sample of flue gas. The pressure gage readings are taken by means of a slightly inclined glass tube, filled with colored alcohol, which projects from the side of the gage box or case. The height of this thread of colored alcohol varies with the pressure, and by means of a scale, marked in the percentages of CO_2 corresponding to certain pressures, the amount of this constituent if the flue gas can be read off at any time. The apparatus is usually provided with accessories by means of which the position of the end of the thread of colored liquid is continuously photographed on a recording cylinder, and thus a permanent record of the CO_2 variations is obtained.

The Telezometer Recorder

The principle upon which the Telezometer recorder is based is similar to that of the Krell recorder—the variations in pressure caused by the differences in density of the ordinary air and of the flue gases being measured and recorded. The gases in this case are drawn by two centrifugal fans worked by a constant speed electric motor, through the bells marked 1, 2, 3 and 4 in Fig. 4. In this figure the bells are shown diagrammatically floating in separate vessels, but in the real instrument 1 and 2 are immersed in one tank, and 3 and 4 in another, paraffine oil being employed as containing fluid.

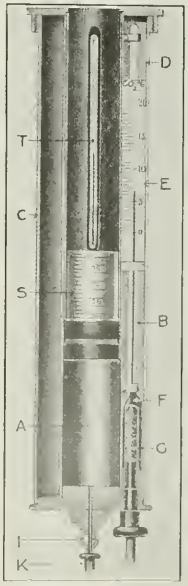

FIG. 1. THE CO_2 THERMOSCOPE

The differences of pressure cause movements of the lever *W*, which are transferred to the pen *T*, and a record of this movement is obtained upon the clockwork chart shown at *X*. The regulation of the inlet and outlet pressures of the air fan is carried out by means of a pin-valve, and by aid of this the instrument is adjusted to the zero position, when both fans are circulating air through the bells.

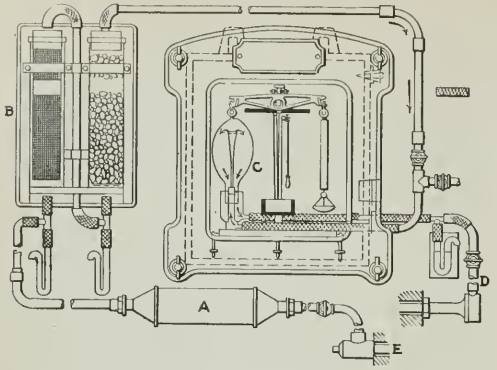

FIG. 2. ARNDT'S GAS BALANCE OR ECONOMETER

The Haber-Loewe Refractometer

The Haber-Loewe refractometer is based upon the measurement of the refractive index of the mixed gases. The method is therefore an optical one and resembles the optical methods for determining temperatures. The refractometer is illustrated in Fig. 5, and consists of the following essential parts: a prism, a telescope and a microscope. The gas to be tested is drawn through the prism, which is made of varnished metal and is provided with windows on opposite sides for the incident and reflected rays of light to enter and escape. The gas used for comparison flows through a casing. When an observation is being made with the instrument, the observer sees in the field of vision a scale, which is partly illuminated and partly in darkness. In pure air the boundary of the dark zone would coincide with zero on the scale, in air containing 0.9 per cent CO_2 this boundary would coincide with 1.0 on the scale, and the line of demarcation between the light and dark zones would be still further shifted for higher percentages of CO_2. The instrument can therefore be graduated to yield the percentage of CO_2 directly by observation, and if desired it can be provided with a photographic attachment for obtaining a permanent record, similar to that used for the Krell apparatus. The refractive indices upon which the instrument is based are the following:

Hydrogen	1.000139	Carbon monoxide	1.000340
Aqueous vapor	1.000261	Methane	1.000444
Oxygen	1.000270	Carbon dioxide	1.000452
Dry air	1.000291	Acetylene	1.000610
Nitrogen	1.000297	Ethylene	1.000678

Comparative Advantages and Disadvantages of the Various Types of Instruments

The first seven automatic gas-testing instruments described in Article II depend in each case for their action upon the absorption of the CO_2 by caustic potash, caustic soda or caustic lime and upon the measurement of the change in volume of the gas before and after this absorption.

The chief advantages of this type of recorder are that it is generally simple in construction and in its method of operation and that its running costs are low. Some of the instruments of this type are made entirely of metal and possess no glass parts or rubber connections, points in their favor which will appeal to all engineers, though not to chemists, who prefer to see

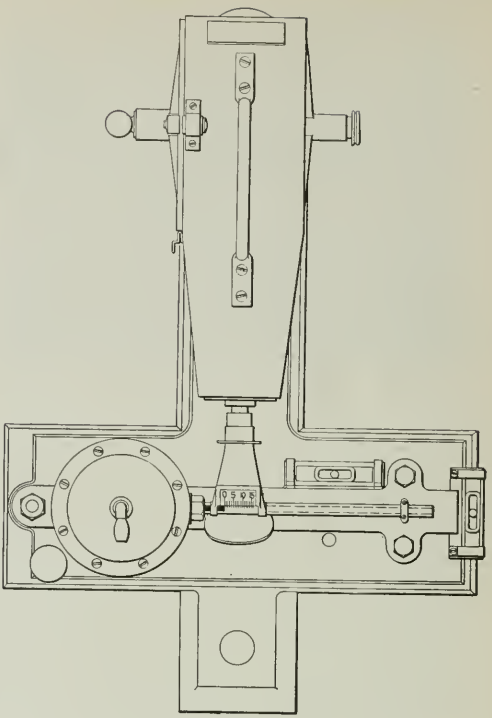

FIG. 3. PLAN OF THE KRELL CO_2 RECORDER

the inside of any apparatus they employ. For use therefore in those works where the gas-testing is in the hands of engineers the Simmance-Abady and bimeter recorders are probably the most suitable and the least likely to get out of order, while the Webster "combustion indicator" is another instrument with metal parts which has found favor with engineers in the north of England.

One of the disadvantages, however, of employing metal with caustic potash solutions is referred to on page 45 of the Report of Barkley and Flagg's investigation (Bulletin No. 91, Bureau of Mines, 1916) and it is therefore not surprising that chemists prefer the forms of apparatus of the Ados or Sarco type, in which

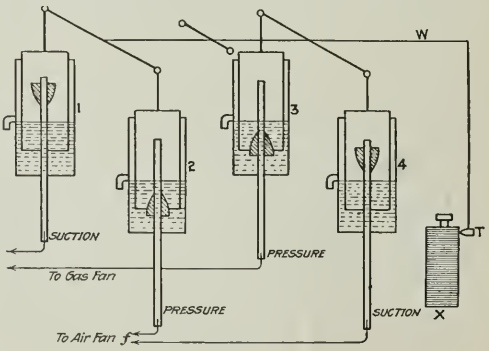

FIG. 4. THE TELEZOMETER CO_2 RECORDER

only glass and rubber are employed for construction of the principal parts of the instrument.

As regards the choice of absorbing media, the bimeter recorder, which uses caustic lime, is under present conditions much the least expensive to work, for caustic potash has increased enormously in price since the war, and it has been replaced in many instances by the cheaper but less satisfactory sodium hydrate.

The last five gas-testing instruments described in this article depend upon the measurement of some physical property of the waste gases, such as weight or refractive index, and do not require any absorbing medium for the CO_2. They are therefore cheaper to operate than the other type of instrument, for not only is the cost of caustic potash or other chemical saved, but the time taken up by recharging is dispensed with. Instruments of this type, however, call for more skill and scientific knowledge in their handling and control, and are more adapted for scientific observations and investigations than for regular use in the boiler house. It is noteworthy, and perhaps characteristic, that the more practical forms of apparatus depending upon the absorption of the CO_2 are chiefly of English and American design and manufacture, while those based upon the very exact measurement of some physical constant of the mixed gases are of German origin.

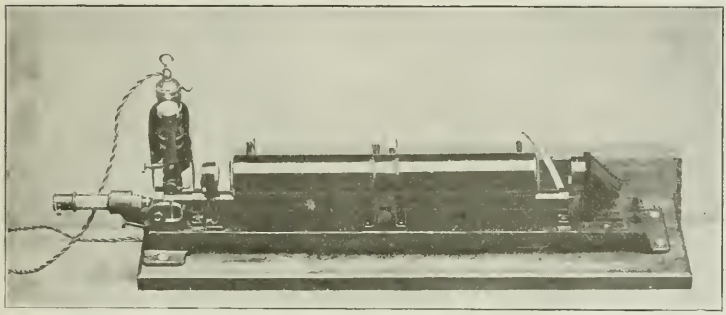

FIG. 5. THE HABER-LOEWE REFRACTOMETER FOR TESTING FLUE GASES

Checking the Results Obtained by the Automatic Recorders

The great advantage of automatic gas-testing apparatus is that it enables a constant and continuous check to be kept on the work of the stokers in place of an intermittent one, and also that it enables the chemist or chemical engineer in charge of the boilers to obtain hundreds of tests upon which to base his judgment of the efficiency with which they are being worked, in place of the few that would be possible without its aid.

As already pointed out, however, the records obtained by the automatic apparatus are not absolutely trustworthy when the boilers are being operated with a narrow margin of excess air, and at other times the CO_2 percentages recorded are too low, owing to the exhaustion of the caustic potash solution or to some other cause. The chemist or chemical engineer in charge of the boilers ought therefore to have an ordinary Orsat gas-testing set in regular use for taking and testing snap-samples of the waste gases, and when discrepancies have been found between the results of these snap-tests and the continuous records obtained by the automatic apparatus, the cause of these differences should be at once investigated and remedied. The Orsat gas-testing apparatus, in its latest form, has been illustrated and described before in these pages, and there is no need to repeat the description in this article; a few notes, however, upon its use for checking the automatic gas test results may be useful.

In the first place it is better to keep the Orsat apparatus in the laboratory and to collect the gas samples to be examined by the dry method in the usual form of gas-sample tube, holding 220 cc. and provided with glass stopcocks at each end. Fig. 6 shows a sampling tube of this type (*A*) connected to the small rubber hand pump (*C*) and valve (*B*) by aid of which snap gas samples can be collected at any point in a few minutes. About six times the volume of gas contained in the sampling tube must be aspirated through it in order to remove all the air, and by measuring the volume of water sucked in by one compression of the hand pump it is possible to calculate how many compressions are necessary to aspirate 1400 cc. of air or gas.

When the gas is very smoky, it is advisable to put a plug of glass-wool in the tube connecting the sample

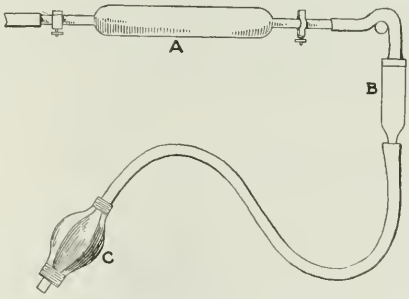

FIG. 6. GAS SAMPLING TUBE AND PUMP WITH CHECK VALVE

tube to the flue or other point whence the gas is being drawn. Half-a-dozen gas samples can be collected in this way with a minimum expenditure of time and trouble, and if the date, hour and place where taken be marked on the label of each tube, the actual testing can be deferred to any convenient time. With the stopcocks closed, the tubes are quite gas-tight and since no water or other liquid is present, beyond that which is contained as moisture in the gas, no absorption of the CO_2 or CO can occur, even if the sample be kept for hours before testing. The tubes, however, must not be placed in direct sunlight while their contents are waiting to be tested, as this may produce chemical changes in the gases.

For checking the work of CO_2 recorders the samples

must be taken from a point in the connecting tube between the filter and the automatic apparatus, as close to the latter as possible, a T piece being fixed permanently here, with a glass stopcock, for this purpose. The two tests of the automatic apparatus, the one just before and the other just after the period when the sample was withdrawn, should be noted on the label of the sample tube, together with the number of the recorder and the time and date of sampling, so that even when a large number of check tests are being carried out at one and the same time there will be no danger of confusing the results. Check tests of this kind should be carried out at regular intervals, say weekly, and also whenever a recorder seems to be working badly or is giving unexpected results as regards the percentages of CO_2.

Frequent Checks Advisable

When the boilers are being worked with a very narrow margin of excess air, in the attempt to attain high efficiencies, that is, with 12 to 14 per cent CO_2, it will be necessary to test more often with the Orsat apparatus, for if carbonic oxide gas or unburned hydrocarbon gases be allowed to escape with the waste gases, the heat losses from this cause may far exceed the heat saved by reducing the excess air.

An empirical method of judging, from the results of the CO_2 and oxygen tests, whether any unburned or imperfectly burned gases are present, is given below, but it is better, of course, to carry out the complete gas analysis and to estimate the carbon dioxide, carbon monoxide, oxygen and hydrocarbons separately in the gas mixture.

The use of the combustion method of determining the carbon monoxide and hydrocarbons is preferable to the methods depending upon absorption by cuprous chloride and fuming sulphuric acid respectively. In this case, only two absorption solutions and pipettes are required, namely, caustic potash and pyrogallic acid, and the

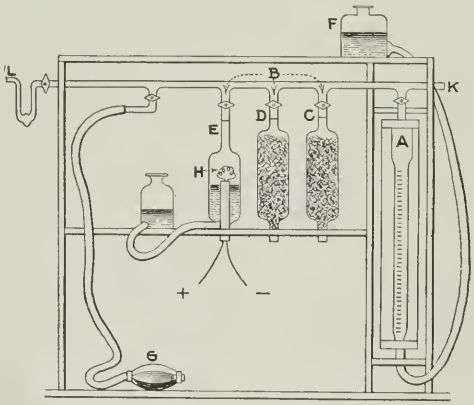

FIG. 7. IMPROVED ORSAT GAS-TESTING APPARATUS

Orsat apparatus can be reduced in bulk and size, and its operation much simplified. Details of the modified apparatus (see Fig. 7) will be found in the Handbook named below.[1]

[1] "Fuel, Water and Gas Analysis for Steam Users," by J. B. C. Kershaw, 2nd edition Constable & Co., 1918.

An Empirical Method of Determining Whether Unburned Gases Are Present in the Waste Gases From Boilers

Air contains by volume 79 per cent nitrogen and 20.8 per cent oxygen. When burning a bituminous fuel of average quality, yielding 35 per cent volatile matter when heated, about 1.8 per cent. of the oxygen

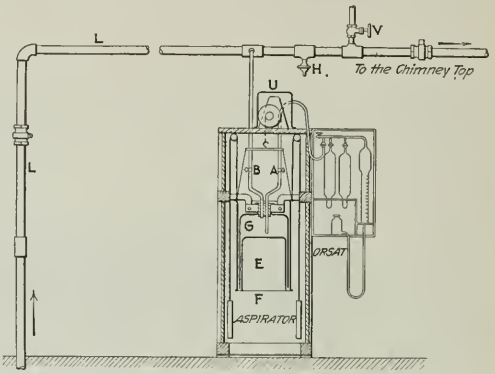

FIG. 8. SAMPLING APPARATUS FOR FLUE GASES, USED IN HAMBURG

of the air will be required to complete the combustion of the hydrogen contained in the coal; the air that remains will therefore contain only 19 per cent of free oxygen. Now any volume of oxygen yields the same volume of CO_2 on combustion, and the tests for carbon dioxide and for oxygen, when added together, ought therefore to total 19 per cent. If there be a continued deficiency in the two tests when dealt with in this manner, it indicates that carbon monoxide or hydrocarbon gases are also present in the exit gases. When burning coke or anthracite fuels, which contain only a small percentage of hydrogen and volatile hydrocarbons, this disappearance of oxygen does not occur. The CO_2 and oxygen tests of the waste gases in such cases, when added together, should equal the original oxygen contents of the air, namely 20.8 per cent.

An Automatic Sampling Apparatus for Obtaining Average Samples of the Waste Gases

When the boilers are being regularly worked with the minimum amount of excess air, it is advisable, however, to institute some more regular and systematic method of checking the presence of unburned gases than that afforded by occasional snap samples, and it is wiser to install the continuous form of sampling apparatus described below. This apparatus was introduced by the Hamburg Smoke Abatement Society some years ago, in connection with the system of boiler control worked in that town and its environs, and it is stated to have given good results, more than 400 boilers under the control of the society having been equipped with it. The apparatus is shown in diagram form in Fig. 8.

The sample of gas is drawn continuously, using natural or artificial draught, from the exit-flue by means of the pipe *L*, and as it passes over the aspirator *F* a small proportion of the gas flow is sucked down into this by the action of clockwork on the bell *E*. The aspirator above this bell is filled with water covered with a film

of paraffine oil,[2] and the rate at which the bell sinks and the gas is sucked into the space *G* above it is controlled by a pendulum and simple clockwork arrangement at *U*, the speed of which can be varied to suit the length of the firing shift. At the end of twelve or eight hours (i.e. when the firemen change) the clockwork is stopped and the average sample of gas stored in the space *G* is tested for carbon dioxide and for oxygen, by aid of the Orsat apparatus shown on the right-hand side of the aspirator, a rubber tube being employed to connect the aspirator and the Orsat apparatus. Two tests of the average samples of gas are made, and the aspirator is then emptied by raising the bell *E*, and by opening the tap *A* and the two taps shown at the entrance to the Orsat apparatus.

By closing *A*, and opening *B*, and by starting the pendulum of the clockwork again, the apparatus is set for taking the next average sample, no attention being required again for eight or twelve hours, according to the length of the working shift. The pipe *L* is kept free from soot and rust deposits by blowing steam or compressed air through it, by means of the tap at *V*, and snap samples of the exit gas can be taken when desired without stopping the aspirator, by connecting the cock at *H* with the tap at the entrance to the Orsat apparatus, by means of a thick rubber tube.

Chemical Trade Statistics

The foreign trade committee of The Chemical Alliance, Inc., is preparing a digest of the chemical export statistics of the seven chemical producing countries the combined exports of which represent 90 per cent of the world's business. Six of these require recalculations from foreign values, weights and measures into our standards. The 100 items to be listed are:

ACIDS AND HEAVY CHEMICALS

Muriatic acid
Sulphuric acid
Nitric acid
Acetic acid and acetates
Glauber's salts
Blue vitriol
Green vitriol
White vitriol
Litharge
Alum and aluminium
Sulphate
Sodium nitrate
Sulphur
Manganates and permanganates
Water glass
Sugar lead
Zinc chloride
Tin salts
Chromates
White lead
Blanc fixe
Zinc oxide
Zinc dust
Lithopone
Barium salts
Barium chloride
Barium nitrate
Barium peroxide
Chloride of zinc
Barytes
Ensom salts
Phosphates of soda
Niter cake
Sal ammoniac
Sulphides of soda and potash

COAL AND GAS BY-PRODUCTS

Gas liquor
Oxalic acid
Ammonium sulphate
Coal tar, coal tar oil and coal tar products
Coal tar pitch
Benzol (coal benzine)
Naphthalene
Anthracene
Phenol (carbolic acid phenyl alcohol)
Cresol (methyl phenol so-called 100 per cent crude carbolic acid of commerce)
Other light, coal tar oils (cumol toluol), etc., carburetted hydrogen, anthracene oil, carbolic oil, creosote oil and other heavy coal tar oils; mineral naphtha (asphalt naphtha)

ELECTROCHEMICALS

Bromine and bromides — Phosphorus — Bleaching powdel

FERTILIZERS

Phosphates of soda
Superphosphates
Natural phosphates of lime
All other fertilizers

MISCELLANEOUS CHEMICALS

Chrome alum
Ultramarine and like blues
Guncotton pyroxyline
Quinine
Glycerine, crude and refined
Cyanides
Prussian and like blue
Insecticides
Unenumerated, etc.
Iodine and iodine compounds

ALKALIES

Soda ash — Soda crystals — Soda bicarbonates — Soda caustic

DYESTUFFS AND INTERMEDIATES

Benzoic acid
Salicylic acid and salicylicates
Aniline and other coal tar dyes
Alizarine dyes
Naphthol-naphthylamine
Naphthylamine
Naphthol
Anthracine dyes and alizarine
Indigo
Acetanilid
Aniline (aniline oil)
Aniline salts
Anthraquinone, nitrobenzol, toluidine, resorcine, phthalic acid and other coal tar products

TANNING EXTRACTS

Extract of oak — Extract of chestnut — Extract of sumac
pine — gallnut — quebracho

This report requires 113,400 tabulations, of which 97,200 have to be recomputed.

[2]Recent investigations have shown that paraffine oil is not so inactive as was supposed toward gases, and brine is better for the purpose of collecting flue gas samples.

Imports and Exports

The following imports and exports for the month of December, 1918, are reported by the Special Statistical Service Section, Division of Statistics, Bureau of Foreign and Domestic Commerce, Department of Commerce:

IMPORTS OF TUNGSTEN-BEARING ORE

Countries	Tons	Value	Countries	Tons	Value
Mexico	4	$6,440	China	244	$258,720
Argentina	42	66,243	Hongkong	526	571,451
Bolivia	25	33,825	Japan	12	18,218
Chile	100	133,525			
Colombia	35	42,700	Total	1,033	$1,184,569
Peru	45	53,447			

U. S. EXPORTS OF TUNGSTEN AND FERROTUNGSTEN METAL, BY COUNTRIES

Countries	Lb.	Value
Canada	2,000	$4,400
Argentina	225	770
Total	2,225	5,170

IMPORTS AND EXPORTS OF LEAD AND ZINC, BY COUNTRIES

Articles and Countries	Gross Weight Tons	Contents, Lb.	Value
IMPORTS:			
Lead Ore:			
Canada	180	277,200	$14,553
Mexico	11,618	153,185	7,407
British South Africa	526	259,529	20,892
Total	12,324	689,914	$42,852
Lead Bullion and Base Bullion:			
Mexico	15,383,544	14,946,348	803,483
Zinc Ore and Calamine:			
Canada	1,172	932,866	19,082
Mexico	2,732	2,005,415	45,101
Total	3,904	2,938,281	64,183
FOREIGN EXPORTS:			
Lead, Pigs, Bars, and Old, total		671,227	$45,206
DOMESTIC EXPORTS:			
Lead Pigs and Bars, product of domestic ore		4,441,279	368,980
Lead Pigs and Bars, product of foreign ore		6,411,949	437,060
Zinc Spelter Cast in Pigs, product of domestic ore		13,131,377	1,368,591
Zinc Spelter Cast in Pigs, product of foreign ore		3,272,856	263,711
Zinc, Rolled in Sheets, Strips, Etc.		3,861,040	488,122

IMPORTS AND EXPORTS OF PLATINUM AND IMPORTS OF IRIDIUM ETC., BY COUNTRIES

Imports of Platinum and Iridium

Countries	Ore and Unmanufactured Platinum Oz. (Troy)	Value	Ingots, Bars, Plates, Sheets, Wire, Etc., of Platinum Oz. (Troy)	Value	Vases, Retorts, Etc., of Platinum Oz. (Troy)	Value	Iridium, Osmium, Palladium, Etc. Oz. (Troy)	Value
England			27	$2,928			1	$123
Canada	3	$315	22	2,332			134	12,486
Panama			456	38,790

Canada			$1,342

Recent Chemical and Metallurgical Patents

Making Pyroxylin Compounds.—In attempting to substitute certain non-volatile liquids for camphor in pyroxylin compounds, it has hitherto been thought necessary to remove the water from the pyroxylin before combining with the liquids. WILLIAM G. LINDSAY of Newark, N. J., has made the interesting discovery that these liquids, if mixed with wet pyroxylin, remain in the mixture when the latter is subjected to pressure between bibulous pads, while the water is entirely eliminated from the press-cake. The resultant dried cake has all the valuable properties of camphor pyroxylin compounds. Liquids mentioned as being suitable for this purpose are: benzyl benzoate, tricresylphosphate, castor oil and mixtures such as camphor, 35 parts with triphenylphosphate, 65 parts; camphor and fusel oil. (1,292,819; assigned to the Celluloid Co.; Jan. 28, 1919.)

Concentrating Nitric Acid.—Mixed nitric and sulphuric acids, such as the mixtures resulting from nitration processes, are introduced at the top of a cylindrical brick lined steel tower, having a central opening filled with pieces of quartz. Steam admitted at the bottom of the tower vaporizes the nitric acid, while the water is retained to a very large extent by the sulphuric acid. The nitric acid vapors pass to a condenser, which is so arranged that the uncondensed vapors are led off to an absorption tower in which they react with water to form dilute nitric acid. This is returned to the first tower for concentration. When applied to mixtures containing not less than 64 per cent sulphuric acid and from 3 to 25 per cent nitric acid, the process yields a product which is 90 to 97 per cent HNO_3. (1,292,948; FRED C. ZEISBERG, assignor to E. I. du Pont de Nemours & Co.; Jan. 28, 1919.)

Recovering Solvent From Colloided Nitrocellulose.—The usual method of recovering ether and alcohol used as solvents for nitrocellulose in the manufacture of smokeless powder results in a loss of a certain percentage of the solvents, in spite of the fact that about fourteen days are required to complete the four operations necessary. A process, which recovers a higher percentage of the solvents in two days, has been devised by WILLIAM F. NASH of Kenvil, N. J. The basic principle of the invention is the displacement of the ether by alcohol and the subsequent displacement of the alcohol by water. The apparatus consists of three tanks, which we will designate *A*, *B* and *C*. *A* and *B* are equipped with fractionating columns; *B* and *C* have steam coils. By means of suitable valves and connections, a single pump is able to circulate liquid either through tanks *A* and *B*, or all three in series, as desired. The nitrocellulose is placed in *A* and the ether displaced by circulating alcohol at 55 deg. C. from *B* through the guncotton, which is preferably in the form of pellets. The ether vapors pass through the fractionating column on *A* into the storage tanks. When the ether content of the pellets has been reduced to the proper value, the valve between the fractionating column on *B* and tank *B* is opened and the liquid in *B* brought to the boiling point. The connections are now arranged in such a manner that the liquid from *A* passes to *B*, where the alcohol is vaporized and conducted through the column to the storage tank, while the liquid refluxed from the column is led into *C*, where a quantity of water equal to the alcohol distilled off is added. This diluted alcohol is kept at a temperature of from 50 to 55 deg. C. and is pumped to tank *A*, thus maintaining a constant circulation of liquid, the alcohol content of which is constantly diminishing. When the material in *A* has had enough solvent extracted to give the required residual solvent when dried, the circulating liquor is all collected in *B* and the remaining solvent fractioned off. The nitrocellulose is now dried in the usual manner. (1,293,515; assigned to Hercules Powder Co.; Feb. 4, 1919.)

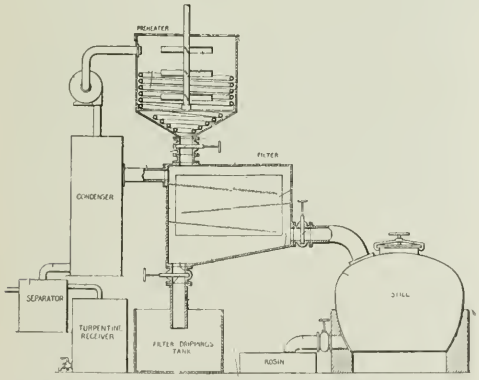
Refining Zinc Pigment.—L. E. WEMPLE of St. Louis, Mo., proposes to remove compounds deleterious to the tinctorial properties and permanency of zinc pigments made from impure raw materials. He purposely makes a first fume containing zinc sulphate, finding that objectionable lead and cadmium oxides cannot exist in conjunction with such excess. This fume is then mixed with pulverized lampblack and roasted for 30 min. in a muffle hearth at between 900 and 1200 deg. F. By a combination of reactions, the carbon reduces the excess of zinc sulphate without attacking the lead and cadmium sulphates, eliminating any arsenic and antimony compounds at the same time. At the end of the required roast, stirring is continued during a quick cooling, when excess carbon is burned out, and SO_2 and other occluded gases are largely eliminated. The method avoids coarsening of grain and recrystallization accompanying excessive heating and prevents the formation of objectionable carbonates. (1,292,976; assigned to American Zinc, Lead & Smelting Co.; Jan. 28, 1919.)

Refining Nickel-Copper Matte.—When bessemerized nickel-copper matte is ground to 60 mesh, roasted, reground, and heated with dilute H_2SO_4 at 80 deg. C., some 70 per cent of the copper is dissolved, with a little of the nickel. CARL and OTTO SANGER, of Clydach, Wales, patent a further separation as follows: The filtered residue is then mixed with 140 Tw. H_2SO_4 and heated at 150 deg. C. in cast iron pans, which converts the oxides into water-soluble sulphates. Copper in this solution is now precipitated quantitatively by finely divided metallic nickel, and the clear filtrate electrolyzed, producing copper-free nickel. (1,291,030; Jan. 14, 1919.)

Manganese Steel.—W. G. NICHOLS of Chicago proposes the following method to reuse manganese-steel scrap without great loss of manganese by oxidation or volatilization: Cold scrap, with or without additional 80 per cent ferromanganese, is charged into an electric furnace and heated carefully to about 600 deg. F., and maintained at that temperature until the non-conductive metal has a thoroughly equalized heat. Temperature is gradually raised, without the production of hot spots, until the whole is at 1200 deg. F., when a basic slag is added and a reducing atmosphere maintained so as to prevent loss in manganese. Gradually the temperature is raised to the

fusion point of the steel, and is kept without superheating until a short time before tapping. Such an alloy can be made into castings, or used as an addition to converter metal; in the latter case it is recommended that the highly heated blown metal be tapped, the slag skimmed off, the melt weighed, and a computed amount of molten manganese-iron alloy added, the latter formed as above and at a minimum pouring temperature. The resulting temperature of the mixture should then be such as to allow immediate teeming. (1,291,655 and 6; assigned to American Manganese Steel Co., Jan. 14, 1919.)

Distillation of Crude Pine-Resins.—In the manufacture of turpentine, the customary procedure of skimming the melted crude gum in the still prior to distillation is unsatisfactory. The smaller pieces of bark, chips, etc., remain in sufficient quantities to cause the discoloration of the resin during the distillation process, thereby lowering its value. The skimmings themselves are saturated with gum and contain undissolved lumps of gum. In addition to this, during the skimming process, vapors of turpentine escape from the open still, causing a further loss of valuable material. With these difficulties in mind, ROBSON DUNWODY of New Orleans has designed the improved system shown in the accompanying diagram. The crude gum is placed in the preheater and brought to a temperature not exceeding 200 deg. F., by means of the steam coils. It is then stirred vigorously to break up the lumps. Any vapors which are given off during the heating are drawn into the condenser by means of a suction fan. The gum is permitted to flow into the filter chamber, in which the coarser impurities and undissolved lumps of gum are removed



IMPROVED SYSTEM FOR DISTILLATION OF CRUDE PINE-RESINS

by a series of inclined screens of varying mesh. The sloping bottom of this chamber prevents the finer particles of sand, dirt, etc., from entering the still with the gum, which is now free from impurities and unstained, as the temperature at this stage is below that at which the impurities begin to discolor the gum. When a sufficient charge has collected in the still, the preheater valve is closed and the filter chamber drained. During the distillation, the hot vapors of turpentine pass through the filter box on their way to the condenser and melt the gum contained in the material on the screens. This gum, which contains the coloring matter extracted from the impurities, collects in the bottom of the filter chamber, is drained off from time to time and, if desired, distilled independently. The turpentine, as it issues from the condenser, is led into a separator, in which the acid water known in the trade as low wine is removed. At the end of the run, the resin is run out into a receiver and the dry skimmings left on the screens in the filter box are removed and destroyed, as the values have been completely extracted. (1,291,800; Jan. 21, 1919.)

Sintering Ores.—In down draft sintering furnaces (such as Dwight-Lloyd machines) the charge becomes more porous as the flame works downward into the cake, thus allowing an undue excess of air to cut down the roasting efficiency of the machine. The best sintering results are apparently obtained by a slow-burning process, consequently A. H. RICHARDS of Garfield, Utah, proposes to add a fresh layer of ore so timed to intercept the accelerated roasting due to excess air. This layer is then ignited on its top, and the cake then is in two layers, burning independently. The process may be repeated as often as necessary, and if properly done, will produce a continuous, evenly sintered mass, at a high tonnage rate. (1,292,059; assigned to American Smelting & Refining Co., Jan. 21, 1919.)

Roasting by Surface Combustion.—C. D. MCCOURT of London, England, patents the process of feeding a continuous stream of sized material through a suitable shaft, equipped with charging and discharging bells, and injecting into this column, through tuyeres, an explosive gaseous mixture. The speed of the blast must evidently be greater than the velocity of combustion. Temperatures considerably in excess of the ordinary result of such reactions may be had by the accelerated surface combustion. Fusing of the charge may be prevented by using a gaseous mixture of low calorific intensity, or increasing the speed with which the granular mass passes the tuyeres. Oxidizing, reducing, chloridizing or other atmospheres may be produced in this manner. (1,291,965; assigned to Surface Combustion, Inc., Jan. 21, 1919.)

Sulphidizing Roasting.—ARTHUR S. DWIGHT of New York City notes that many natural ores, for instance those of copper, are deficient in sulphur to the extent that after the volatile sulphur has been driven off in heating, not enough remains to form a matte and clean slag. By-products, such as zinc residues and burned pyrite, contain small amounts of valuable metals which could be recovered if properly sulphidized. He has discovered that if sulphur ores be pulverized and mixed with finely divided metals with a strong affinity for sulphur such as copper or iron and heated to a bright red heat, free oxygen being excluded, the unstable sulphur will unite with the metal instead of distilling. He therefore proposes to heat oxidized ores with sufficient carbon to effect the reduction of the metals, and then mix with a pulverized sulphur-bearing ore. The product becomes pasty at a comparatively low temperature, and can be delivered either in lumps for blast furnace work, or finely divided for reverberatory smelting. (1,238,279; Aug. 28, 1917.)

Personal

MR. G. C. BENSON, recently of Nobel, Ont., Canada, has accepted a position with the National Carbide Co. of Toronto as research chemist.

MR. A. S. BLAGDEN has been elected president of the Air Reduction Co., Inc., New York, N. Y.

MR. E. C. CARLYLE has resigned his position as analytical chemist with the Geo. H. Morrill Co., Norwood, Mass., and become associated with the Saarbach Laboratories, Inc., analytical and consulting chemists, New York.

MR. E. T. CASLER, formerly chemist for the Phosphate Mining Co., Nichols, Florida, is now chemist with the Air Nitrates Corp.

MR. WILLIS B. CLEMMITT has joined the engineering staff of the Powdered Coal Engineering & Equipment Co. of Chicago, Ill., in the capacity of advisory engineer. Mr. Clemmitt was formerly assistant superintendent of the open-hearth department of the Central Iron & Steel Co., Harrisburg, Pa.

MR. EDWARD S. DAVIS, chief of the Fuel Oil Section, Bureau of Oil Conservation, after six months of service, has returned to Tate, Jones & Co., Inc., Pittsburgh, Pa.

MAJOR A. C. FIELDNER, Chemical Warfare Service, U. S. A., who was in charge of the gas masks research at the American University Experiment Station, Washington, D. C., has returned to the Pittsburgh Station of the Bureau of Mines, where he will have charge of the chemical research laboratory.

DR. FEDERICO GIOLITTI, director general of the steel works of Giov. Ansaldo & Co., Italy, and of international note as a metallurgist, is now in the United States on business and is making his headquarters in New York City.

MR. C. W. JOHNSON has been appointed assistant manager of works of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

MR. ARTHUR LACHMAN is now connected with the Great Western Electro-Chemical Co., San Francisco, Calif.

CAPTAIN P. E. LANDOLT has resigned from the Nitrate Division, Ordnance Dept., U. S. A., and has returned to his old position as chemical engineer with the Research Corporation, New York City.

MR. H. L. OLIN is now chemist in the research department of The Barrett Company, Edgewater, N. J., having been discharged from the Army at Edgewood Arsenal, where he had the rank of Captain, C. W. S.

MR. SEELY B. PATTERSON, JR., formerly assistant general manager of the Bethlehem Steel Co.'s Cuban interests, has been relieved from duty in the Engineering Corps and is now in Allentown, Pa.

MR. WALTER H. PEARCE, for three years with the Commercial Research Company, New York and Flushing, N. Y., is now metallurgist with Paul G. Niehoff & Co., Chicago, Ill.

MR. GEORGE H. RUPPERT, who, before his entry into the Chemical Warfare Service, had charge of a sodium ferrocyanide department of the Semet-Solvay Co., has accepted a position as advisory engineer with the Powdered Coal Engineering & Equipment Co., Chicago, Ill.

MR. HERBERT L. SHERMAN, formerly president of the New England Bureau of Tests, Inc., and more recently in charge of inspection for the Construction Division of the United States Army, has become a member of the firm of Arthur D. Little, Inc., Cambridge, Mass.

MR. JOSEPH T. TERRY, JR., who for some time past has been engaged in conducting flotation experiments for the American Zinc Co., Mascot, Tenn., has opened an office as a consulting engineer under the title Terry Mining and Metallurgical Corp., at Salt Lake City, Utah.

MR. TAMOTSU WATANABE of Tokyo, Japan, is visiting the industrial centers of the United States in the interests of the Mogi Commercial & Industrial Department.

Obituary

MR. HERBERT R. DRYFOOS, president of the Cleveland Alloys Co., Cleveland, Ohio, died on Feb. 18 at his home, of pneumonia.

LIEUT. ELBERT C. BAKER, the only son of J. T. Baker of the J. T. Baker Co., Phillipsburg, N. J., was killed in action Sept. 30, 1918. Lieut. Baker, a graduate of Cornell University, was engaged as a research chemist in his father's laboratory and during the one year of his employment was doing special work in standardizing methods of analysis for chemical reagents along the lines suggested by the Bureau of Standards.

Current Market Reports

The Non-Ferrous Metal Market

Saturday, March 8. — The non-ferrous metal prices are now on a peace basis with few exceptions, and an active market is expected.

Aluminium: — There is an open market for aluminium and conditions are quiet. Ingots 98-99 per cent are offered at 31c. Sheets, 18 gage and heavier, are 42c. Powder, 100 mesh, 70c.

Antimony:—Wholesale lots are offered from 7c. to 7⅛c. and jobbing at 7¼c. There is no active buying.

Copper:—During the past ten days, 25,000,000 lb. of copper was sold at from 14⅞c. to 14⅝c. per lb. The Government surplus stocks are to be turned back to the producers and a firm market is to follow from now on.

Copper sheets, hot-rolled	lb.	$0.24½—
Copper sheets, cold rolled	lb.	.25½—
Copper bottoms	lb.	.32½—
Copper rods	lb.	.21½—
Copper wire	lb.	.19½—
High brass wire and sheets	lb.	.20½—
High brass rods	lb.	.19½—
Low brass wire and sheets	lb.	.22½—
Low brass rods	lb.	.23½—
Brazed brass tubing	lb.	.31½—
Brazed bronze tubing	lb.	.36 —
Seamless copper tubing	lb.	.31 —
Seamless bronze tubing	lb.	.31 —
Seamless brass tubing	lb.	.30 —
Bronze (gold) powder	lb.	1.00 —

Lead:—The lead market has been quiet but firm and indications point to activity in the near future. E. St. Louis quotes 5c. and New York, 5½c. lb. Sheet lead, 8c. lb.

Tin:—The U. S. Steel Products Co. has liquidated over half of its 10,000-ton allotment at 72½c.

Zinc:—Spelter has taken an extraordinary decline, going from $134.50 to $121 per ton in the last fortnight. Zinc dust, 14c. Sheet zinc, 11c. lb.

OTHER METALS

Bismuth	lb.	$3 20 — $3 65
Cadmium	lb.	1 40 — ...
Cobalt	lb.	2 50 — 3 50
Magnesium	lb.	1 75 — 2 10
Mercury	75 lb.	75 00 — ...
Mercury	lb.	1 50 — ...
Nickel	lb.	40 — 45
Tungsten	lb.	Nominal
Iridium	oz.	175 00 — ...
Palladium	oz.	115 00 — ...
Platinum	oz.	97 50 —100 00
Silver	oz.	1.01⅛— ...

The Iron and Steel Market

War-time prices for steel are about to be deflated as a result of the operation of a plan devised by Secretary of Commerce Redfield and approved by the President. For this purpose the Industrial Board of the Department of Commerce has been organized, with George N. Peek, formerly vice-chairman of the War Industries Board, as chairman. At a meeting of representatives of the iron and steel industry held in New York March 6, Mr. Peek outlined the plan and it was unanimously approved. The next proceeding is the meeting between the board and a committee of the industry, to be held in the week beginning March 17. The reduced schedule of prices may be announced immediately after that meeting, but more likely further time will be required for negotiation and study of conditions.

The Government's object is to deflate prices, particularly prices of commodities involved in building operations. The operation is based on the dictum that "the law of supply and demand cannot cure what it did not create," this being a system of controlled prices for war time, set high for the purpose of stimulating production. When there is no buying, the law of supply and demand does not operate. This is a fact that the steel industry has frequently exemplified, for in periods of light demand it has refrained from reducing prices, maintaining that reduced prices would not stimulate buying.

It is recognized on all hands that the resumption of construction work depends upon the action of no one industry, and that all prices entering into construction work must come down in order to make the proposition attractive to the investor. Accordingly, while the Industrial Board begins with the iron and steel industry, it gives assurance that it will take up all building materials and some other materials as well. No program is mapped out for the distant future, and it is intimated, if not promised, that the activities will be discontinued whenever it is seen that the law of supply and demand is again operating. The proposition is welcomed by the iron and steel industry, though the industry does not advertise the fact, because it affords the opportunity that otherwise might be lacking for making a formal reduction in prices and establishing a level to which individual producers will be disposed to adhere. Without some such formality the iron and steel producers would have the opportunity of adhering to existing prices or nothing and naturally they would choose the former.

Industry Active

Up to this writing the iron and steel industry has, as a whole, experienced no hardships that would make it desirable to reduce prices radically. There has been a very remarkable situation. With practically all branches of the iron and steel market very dull, and with almost all consuming industries presenting the appearance of decided inaction, the production of steel has been very heavy. In proportion to capacity, assumed at 49,000,000 gross tons per annum, production of steel ingots in January was at 85.1 per cent, while production in February was at 83.6 per cent, this statement being predicated upon the trustworthy returns of the American Iron and Steel Industry, covering the monthly output of 29 companies which in 1917 made more than 87 per cent of the country's total output. Production at this writing is but little below the February average.

While it is marvelous that the steel industry should operate at so high a rate, with trade very dull, it is a corollary that nothing like such a rate could be continued for any length of time. In normal times more than half of all the steel produced passes into construction work and scarcely anything along this line is now being undertaken. A peculiar combination of circumstances has made it that there has been an outlet for a remarkable large quantity of steel. Ingot production in February was at the rate of about 40,900,000 gross tons a year, while in no year prior to the war was there an output as great as 31,000,000 tons, and the highest rate attained, for only a few weeks, was about 35,000,000 tons, in the early spring of 1913. At that time much steel was passing into construction work.

While the industries of the country are regarded as relatively inactive, there are some exceptions. The automobile industry is working at top speed, and while it has not yet attained the quantity production of which it is capable the necessary shop changes are nearing completion and materials and accessories are being assembled. The Ford Motor Co., for instance, which originally planned to reach an output of 3000 a day by June 1, has already attained 2500 and expects to reach 3000 by April 1. Steel shipments to the automobile industry are the heaviest on record. In nearly all the oil and gas fields there is great activity and the demand for the "oil country goods" of the pipe mills is fully up to normal. The agricultural implement factories are fairly busy, but in this case no large demand for steel is involved, as the factories had very considerable stocks. Altogether, however, it is difficult, if not impossible, to explain in full where the large steel production has been going.

Pig Iron Declines

In pig iron there has not been the same incentive for maintaining prices as has existed in the case of finished steel products. In the latter there is always a clear cut market, the price being uniformly f.o.b. Pittsburgh plus freight to destination. In pig iron the normal condition is for each district to have its own market, there being many districts, including Alabama, Virginia, eastern Pennsylvania, Buffalo, Cleveland, Chicago and "the valleys"—Mahoning and Shenango. War time control placed all furnaces, irrespective of location, on precisely the same basis, and then last September produced a still more curious alignment by putting Virginia on a Birmingham basis and eastern Pennsylvania on a Pittsburgh basis. As this alignment would certainly be departed from some time, the furnaces have had no great incentive to maintain it. The recommendation of the industry's committee last December, prepared for submission to the War Industries Board but refused consideration by the board because it was about to disband, was that a reduction of $3 be made in pig iron. This recommendation was eventually adopted by the furnaces, but since the beginning of this month there have been some recessions. A Birmingham interest, for instance, cut the recognized price of $31, Birmingham, on No. 2 foundry by $2.75 on an order for 500 tons, establishing $28.25 as the price to be shot at next. At least two eastern Pennsylvania furnaces resumed quoting on the basis of furnace, instead of f.o.b. Pittsburgh, effecting declines averaging about $2 a ton in delivered prices. Two or three valley furnaces, on quite moderate tonnages, quoted $28, furnace, or less, for No. 2 foundry, or $3 under the previously recognized market. Buffalo furnaces adhered to $31, Buffalo furnace, for local trade, but one interest circularized distant markets offering iron on a lower basis. In basic and bessemer no definite declines occurred, possibly because there was no inquiry.

Resale ferromanganese has been available at $150, f.o.b. shipping point, for 80 per cent, against makers' nominal quotations of $200, delivered, for 80 per cent and $170 for 70 per cent. The last established market was $250 for 70 per cent.

There has been only occasional and inconsequential shading of steel prices by producers. Orders have been small individually, and more likely to be placed at full prices than at concessions, for the average buyer once in receipt of a cut price quotation would be moved, not to place the order, but to seek further concessions.

The Chemical Market

Coal Tar Products:—The character of trading in coal tar products has shown little change during the interval, although there seems to have been more inquiries for the various products and producers are looking forward to a resumption of some activity. The textile industry is recovering from its recent slackness and as it is an accepted fact that this has a strong bearing on the color market, this is the best proof for the possibilities of intermediates developing a more firm position in the market. In the meantime, however, small lot transactions continue to feature the market and lower price levels have generally been effected.

Benzol:—The consuming demand for this product seems to be steady, although the various directions report stocks in sufficient quantities to take care of additional business. Producers have lowered their prices 2c. per gallon for tank car material and the reduction also applies to that in drums.

Phenol:—The weak position of the market that has been evident for some time continues and accumulations of large quantities of the product are noted in various directions. Most producers of the product have closed down their plants and some are buying back their own product at low levels to complete their unfilled contracts.

Toluol:—Resale offerings of this product seem to create some buying interest, but from all accounts second hands

seem to have little to offer. Manufacturers report a fair business passing and prices are firmly maintained.

Naphthalene:—The market for the various varieties of this product has undergone no important changes, with no disposition on the part of buyers to purchase beyond their immediate needs and even the drug trade, which is quite a factor at this season of the year, has seemingly not brought its full requirements to the market.

Alpha Naphthol:—Offerings of this product are none too liberal; however, there is no pressure on the part of buyers and no difficulty is experienced in meeting the situation. Prices are firmly maintained for both the crude and refined products.

Aniline Oil:—Another slight reduction in prices has been made by manufacturers of this commodity, who seemingly have accumulated fair quantities of stocks. While a fairly steady business is reported, individual sales noted are of a minor character.

Aniline Salt:—A steady sale is reported, but there has been no resumption of any important activities in the demand, and available stocks are more than sufficient for the current call. Prices, however, are quotably unchanged.

Alpha Naphthylamine:—Prices for this material are steady at the recent decline, but supplies are large enough to cause some concern on the part of producers, while buyers are apparently not interested in any forward stocks.

Benzidine:—There has been nothing in the way of any increase in business for this material and the recent export activity for the base product seems to have eased off, while the sulphate variety appears to be entirely neglected.

Cresol:—Trading continues along quiet lines; however, business is of sufficient volume to avoid any accumulation of stocks, with available supplies generally in proportion to the current call. Dealers have not altered their recent prices, which are firmly maintained.

Diethylaniline:—Trading in this product has been somewhat more active, which was seemingly brought about by some reductions in prices on the part of manufacturers, and transactions for the most part seem to be direct, with little trading noted through second hands.

Metanitraniline:—The market for this material is without special feature and small lot trading continues to constitute the only activity at the moment. However, there is no accumulation of stocks in any important quantity, and prices for the commodity are firmly maintained.

Metaphenylenediamine:—The continued quietness for this product has had its effect and price reductions in most directions are noted, with available supplies more than sufficient for the current call.

Diphenylamine:—Consumption requirements are in no important quantities and there seems to be a fair accumulation of stocks in the various directions, but holders have not altered their recent quotations since the recent decline; however, it is intimated on a firm order some concessions would be made.

Dinitrophenol:—There is little in the way of any important trading for this material and prices seem to be firmly maintained in most directions, although some large lot business was consummated where prices shading was effected.

Dinitrobenzol:—No material changes have developed in this market; trading is of a routine nature and individual sales are confined to small lots. Despite the quietness prevailing manufacturers are firmly maintaining prices.

HEAVY CHEMICALS:—While no important volume of trading overshadowed the market, there seems to have been more export orders about, but this activity was brought to a sudden standstill when the labor strike along the waterfronts was announced. Under these circumstances exporters were not disposed to bring their orders to the market, in view of the possibility of goods being left on docks and subject to other hazardous conditions. On the other hand, local trading continues along quiet lines, with consumers confining their purchasing to immediate needs, expecting lower price levels, but it is an accepted fact that manufacturing costs will not be much lower, especially as to wages, which proportionately reflects in the actual selling prices of many commodities. Most of the business is transacted through second hands, where competition is keen and price cutting is general when there seems to be some actual business at hand, but small lot trading constitutes the only activity in any direction. Caustic soda has attracted little attention on the part of buyers; stocks are seemingly plentiful and the market is rather weak, while the position of soda ash is more firm at the recent decline.

Soda Ash:—The consuming trade seems to be steadily taking a fair portion of supplies, which tends to keep the market rather steady for bag material. Single bags from the warehouse are now quoted at $1.55 to $1.65 by second hands. Barrels are offered at $1.85 ex-warehouse per 100 lb., although some cheap lots seem to be available at most times at $1.75. Double bags at Middle Western shipping points are held at $2.15 to $2.25, with offerings at similar prices at the Pacific Coast.

Caustic Soda:—There has been little interest noted on the part of buyers, who seem to be in a position to close in lots of ten to twenty tons at favorable prices, while round lots would be difficult to close at much less than 3c. per lb. for the 76 per cent solid, despite the fact that limited quantities are freely offered at 2⅞c. to 3c. per lb. Ground caustic seems to be gradually easing off, with offerings made at 3⅞c. to 4c. by second hands.

Cyanide of Soda:—Prices for this commodity are firmly maintained, although there is no unusual activity noted and trading seems to be confined to small lots. Purchasing is generally direct, with the 96-98 per cent material being quoted at 30c. to 31c., while the chloride mixture of 73-76 per cent is held at 25c. to 27c. and the chloride carbonate mixture is quoted at 20c. to 21c.

Chlorate of Soda:—No improvement has been noticed in the call for this product, which appears to be in liberal supply and prices are quotably unchanged ranging from 18c. to 20c.

Chlorate of Potash:—The demand is steady and trading is of sufficient volume to keep the market firm, particularly for the domestic product, which seems to be the most preferable. Prices are steady at 40c. per lb. f.a.s., while the Japanese powdered material is offered at 32c. to 33c. and the crystals at 30½c. to 31½c., according to quantity.

Yellow Prussiate of Soda:—The item continues to be neglected, with no disposition on the part of buyers to purchase forward stocks.

Bichromate of Soda:—The position of this item in the market appears to be gradually weakening, with prices fractionally declining from time to time. First hands quote from 12c. to 12¼c. for spot material with resale offerings being made at from 11½c. to 12c., and sales are reported to be passing at the inside figures in most instances.

Copper Sulphate:—There has been no resumption of any important trading in this commodity and purchasing seems to be confined to immediate needs. Standard brands of the 98-99 large crystals are now offered at 7⅞c. to 8c., while the medium crystals are held at from 7½c. to 7⅝c. for spot material.

Magnesia Calcined:—While consumption requirements seem to be of sufficient volume to keep the high-grade product well sold up, other varieties are apparently more liberal in supply. In most instances, the high-grade light variety is quoted at from 70c. to 75c. for early April delivery, and the medium grade is held at 40c. to 50c., with the heavy variety being offered at from 9c. to 10c.

Yellow Prussiate of Potash:—Small lot trading continues to feature the market and reports from the various directions indicate stocks are in liberal supply. In some instances, in the resale market, there are offerings as low as 55c., with others quoting 58c. to 60c.

Red Prussiate of Potash:—There seems to be little in the way of actual trading in this material and supplies are in sufficient quantity to take care of additional business. Prices for the material are steadily declining, with offerings now held at $1.50 to $1.60.

General Chemicals

WHOLESALE PRICES IN NEW YORK MARKET MARCH 8, 1919

Acetic anhydride	lb.	.90	—	1.00
Acetone	lb.	.15½	—	.16

INDUSTRIAL

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

BIRMINGHAM—The Birmingham Railway Light & Power Co., 2100 1st Ave., has awarded the contract for the installation of new gas making machinery, to the Gas Machinery Co., 1900 Euclid Ave., Cleveland, Ohio. Estimated cost, between $75,000 and $80,000. The company plans to construct an addition to its gas house. J. S. Pevear, general manager.

CHICKASAW—The Tennessee Coal, Iron & Railroad Co. plans to build two ore smelters on its property here, to take care of ore brought from Cuba by the United States Steel Corporation.

California

SAN DIEGO—Olmsted & Gillelen, engineers, 1112 Hollingsworth Bldg., have submitted report to city on sewage disposal plant. Plans include the construction of intercepting sewers to cost $320,000; small pumping station, $32,500; screening plant, $225,000, screens at 32nd St. plant, $25,000; pumps at 32nd St. plant, $4000. A. H. Wright, city clerk.

Colorado

TELLURIDE—The Tomboy Gold Mines Co., Ltd., plans to build a new flotation plant and is in the market for lumber and flotation equipment. Estimated cost, $150,000. D. A. Herron, general manager.

VANADIUM—The Primos Chemical Co. will rebuild its mill recently destroyed by fire, entailing a loss of $100,000.

Connecticut

HAMDEN (New Haven P. O.)—The town has been authorized to issue $100,000 bonds for the construction of sewers and a sewage disposal plant.

District of Columbia

WASHINGTON—The Bureau of Yards & Docks, Navy Department, has awarded the contract for the construction of a laboratory at the Naval Hospital here, to W. E. Mooney, Evans Building. Estimated cost, $16,000.

WASHINGTON—The Bureau of Yards & Docks, Navy Department, has awarded the contract for installing mechanical equipment in hygienic laboratory in the South Building to J. E. Granberry, Fendal Building. Estimated cost, $53,224.

Florida

JACKSONVILLE—The Board of Commissioners of Duval Co. will soon award the contract for furnishing approximately 1500 gallons of arsenical cattle dip, delivered f.o.b., Jacksonville, in such quantities and at such times as may be directed by the County Purchasing Agent.

ST. PETERSBURG—The city has awarded the contract for installing sanitary sewers and two 1-story Cameron septic tanks in the northeastern section of the city to the Southern Construction Co., St. Petersburg. Total estimated cost, $21,395. F. M. Nelson, city engineer.

TAMPA—The McElroy Engineering Co., Giddens Building, will soon receive bids for the construction of a sugar mill and farm, including 20 miles tramway. Estimated cost, $800,000. Owner's name withheld.

Georgia

SAVANNAH—The Reliance Fertilizer Co., 106 Bay St., plans to build a fertilizer plant. Estimated cost, $100,000. Lockwood Greene & Co., Healey Building, Atlanta, engineer.

Illinois

CHICAGO—The Armour Soap Works, 31st and Benson Sts., plans to build an addition to its distilling plant. Estimated cost, $35,000. R. C. Clark, architect, care owners, is receiving bids.

CHICAGO—The Municipal Tuberculosis Sanitarium, Crawford and Bryn Mawr Ave., will soon award the contract for the construction of a 2-story, 57 x 123.8 ft. laboratory and connecting tunnel, including sterilizing, serum and operating rooms, etc. Total estimated cost, $75,000. J. Hunt, 30 North Michigan Ave., architect.

EAST ST. LOUIS—The Obear Nestor Glass Co., Broadway and Terminal R.R., has awarded the contract for rebuilding part of its factory destroyed by fire, to Ferdinand Ganschinietz, 501 North 18th St. Estimated cost, $65,000.

LINCOLN—The Illinois China Co. will build a 5-kiln pottery plant, and install kilns and drying shed. A. Smith, manager.

WOODRIVER—The Board of Education will install equipment for the chemical and physical laboratory in the 2-story, 90 x 150 ft. high school which it plans to build. Total estimated cost, $90,000. J. W. Kennedy, Cahokia Bldg., East St. Louis, Engr.

Indiana

FT. WAYNE—The city plans to build a dam, filtering and purifying plant, having a capacity of 12,000,000 gals. Estimated cost, $500,000. H. W. Becker, clerk of the board of public works. C. H. Hurd, 807 Merchants Bank Building, Indianapolis, engineer.

HAMMOND—The city plans to build a water filtration plant. W. Bridge, city engineer.

Iowa

HURON—The Board of Education will receive bids until March 20 for the construction of a 2-story, 60 x 72 ft. high school building, including laboratories, auditorium, etc. Estimated cost, $50,000. N. Schrock, Oakville, president. H. C. Eckland & Co., McKinnie Building, Moline, Ill., architect.

Maryland

BALTIMORE—The City Water Department plans to build a new filtration plant, having a capacity of 120,000,000 gals. per day, as an addition to the existing filtration plant at Lake Montebello, which has a capacity of 128,000,000 gals. per day; also construct experimental filters for comparing the efficiency of mixing coagulants at the Montebello filters. W. E. Lee, City Water Engr.

CURTIS BAY (Baltimore P. O.)—The Mexican Petroleum Co., 120 Broadway, New York City, N. Y., plans to build a large refinery here. Estimated cost, $1,000,000.

Missouri

ST. LOUIS—The J. C. Finck Mineral & Milling Co., 101 Barton St., will build a 2-story, 78 x 105 ft. addition to its barytes milling plant. Estimated cost, $8,000. C. P. Delore, engineer.

ST. LOUIS—Gerst Bros. Meat Co., 3823 Lucky St., has awarded the contract for the construction of a lard rendering and cooling plant to Gillespie & Daly Co., International Life Building. Estimated cost, $20,000.

ST. LOUIS—The Monsanto Chemical Co., 2nd and Lafayette Sts., will build a 1-story, 62 x 176 ft. factory at 102 Lafayette St. Estimated cost, $20,000. L. Veillon, 2nd and Lafayette Sts., engineer.

Nebraska

LINCOLN—The city plans an election April 8 to vote on a $100,000 bond issue for the construction of 4½ miles of collecting and intercepting sewers and sewage disposal plant. A. Dobson, 945 D St., engineer.

Michigan

THREE RIVERS—The Eddy Paper Co., White Pigeon, plans to build a new plant here. Estimated cost, $1,750,000.

New Jersey

MILLTOWN—The Elizabethtown Water Co., 68 Broad St., Elizabeth, plans to build a pumping station and filter house near here. M. Sherrerd, engineer.

NEW BRUNSWICK—The Eastern Potash Co., 120 Broadway, New York City, N. Y., will build a potash plant here consisting of ten buildings. Estimated cost, $2,000,000.

New York

BATH—The County Dairymen's League will install laboratory equipment and an ammonia system in the dairy plant which it plans to build here. Total estimated cost, $150,000. M. W. Davison, director.

NEW YORK—Frank Dowling, borough president, has awarded the contract for furnishing and delivering 40,000 gals. of gasoline to the Tidewater Oil Co., 11 Broadway. Estimated cost, $9800.

BROOKLYN—The State Hospital Commission, Capitol, Albany, received bids Feb. 19 for building a sewerage disposal plant at the Brooklyn State Hospital, here, from Murphy Bros., 262 Bay 43rd St., Brooklyn, $22,483 (200 days). L. F. Kelly, Inc., 296 Stuyvesant Ave., Brooklyn, $22,540 (200 days); J. L. Sigretto & Co., 455 Woodhaven Ave., Woodhaven, $23,000 (200 days). Noted Feb. 15. The contract was awarded to Murphy Bros.

CHITTENANGO—The Building Commission of the Dairymen's League will install laboratory equipment in the modern milk handling plant which it plans to build. Estimated cost, $20,000.

CORTLAND — The Dairymen's Local League will install laboratory equipment in the modern milk plant which it plans to build here. Estimated cost, $50,000. W. F. Webb, president.

ROCHESTER—The Dairymen's League plans to install laboratory equipment in the milk handling plant which it plans to build for the city. Total estimated cost, $150,000. G. M. Tyler, president.

TUCKAHOE—The Hodgeman Rubber Co. plans to build a 1-story, 50 x 150 ft. factory. W. L. Stoddard, 9 East 40 St., New York City, architect.

UTICA—The State Hospital Commission, Capitol, Albany, received bids March 4 for the construction of a 2-story, 44 x 60 ft. laboratory and mortuary at the State Hospital here, from La Porte & Goodman, Albany, $23,900; J. Gleason, Ilion, $26,970; Kimberly Construction Co., Mayro Building, $28,573. Noted Feb. 15.

WILLARD—The New York State Hospital Commission plans to build a chlorinating plant at the Willard State Hospital here. F. L. Warne, steward; L. F. Pilcher, Capitol, state architect.

North Carolina

WILMINGTON—Morris & Co., 38 South Dearborn St., Chicago, Ill., plans to build a fertilizer factory on a site recently purchased here.

Ohio

CLEVELAND—The Reflex Ignition Co., 1708 Payne Ave., has increased its capital stock from $100,000 to $250,000 and plans to build an 80 x 160 ft. plant.

SILVER LAKE (Bellefontaine P. O.)—The village plans an election soon to vote on a $26,000 bond issue for the construction of a sewage disposal plant. E. A. Tewksbury, clerk.

SPRINGFIELD—The city plans to build a sewage disposal plant.

Oklahoma

DUNCAN—The city will soon receive bids for the installation of new machinery for the sewage disposal plant. Estimated cost, $10,000. Benham Engineering Co., Colcord Building, Oklahoma City, engineer.

OKLAHOMA CITY—The Magnolia Petroleum Co., 212 Oklahoman Building, will soon award the contract for the construction of a 1-story gasoline refinery. L. H. Bailey, 1214 North Oklahoma St., architect.

Oregon

MOLALLA—The Molalla Fire Clay Co. plans to build a 1-kiln pottery factory on a 32-acre site, northwest of here, recently donated by the city. B. S. Sinoheimer, secretary.

Pennsylvania

CLARENDON—The Tiona Refining Co. plans to rebuild its plant here recently destroyed by fire.

HUNTINGDON—The borough has retained Gannett, Seely & Fleming, Engr., 204 Locust St., Harrisburg, to make a detailed study, report and plans for complete

rehabilitation and purification of the borough water supply. A filter plant will probably be built.

MANHEIM—The U. S. Asbestos Co. plans to build a 1-story, 60 x 100 ft. and 50 x 200 ft. addition to its plant, to provide for increased capacity

PHILADELPHIA—The Babies Hospital of Philadelphia, 1126 Walnut St., will install a chemical laboratory in the 7-story, 41 x 91 ft. hospital which it plans to build on 7th and Delancey Sts. Total estimated cost, $80,000. C. A. Ziegler, Bailey Bldg., architect.

PHILADELPHIA—Powers, Weightman & Rosengarten, 916 Parrish St., have awarded the contract for the construction of a 4-story, 28 x 40 ft. factory for the manufacture of chemicals, to R. C. Ballinger & Co., 218 North 13th St. Estimated cost, $30,000.

TEMPLE—The Temple Malleable Iron & Steel Co. has awarded the contract for the construction of a 1-story, 340 x 380 ft. plant near the Schuykill Division of the Penusylvania R.R., to F. D. Chase, People's Gas Building, Chicago, Ill. Plans include the installation of a chemical laboratory to use electro-metallurgical process. Total estimated cost, $350,000.

WILKES-BARRE—S. T. Romberger Co., Franklin Junction, plans to build a 2-story, 24 x 30 ft. rendering plant. Estimated cost, $10,000. C. Wannenwesch & Co., 563 Williams St., Buffalo, N. Y., architect.

South Dakota

HILL CITY—The American Tin Mining Co. is in the market for a Telsmith gyratory crusher, a Hardinge conical ball mill, three Richards pulsator classifiers, one settling cone, an electric furnace, two oil storage tanks and other equipment. Estimated cost, $21,000.

Texas

WACO—The Riverside Oil & Refinery Co., Oklahoma City, Okla., plans to build an oil refinery having a daily capacity of 1500 bbl.

RANGER—The city plans to build a distilled water plant. Estimated cost, $10,000. W. M. Powell, manager.

Virginia

NORFOLK—R. T. Lipscombe, 34 Virginia National Bank Building, and others plan to build a dehydration, ice and cold storage plant. Estimated cost, $225,000. B. Mitchell, Seaboard Bank Building, architect.

West Virginia

CLARKSBURG—The Clarksburg Water Board has awarded the contract for the construction of an addition to the mechanical filtration plant to the American Water Softener Co., 1011 Chestnut St., Philadelphia, Penn. Noted Mar. 4.

MARTINSBURG—The city plans to build sewerage system to include a sewage disposal plant. T. W. Sparrow, city engineer.

British Columbia

VANCOUVER—The Tudhope Electric Metals, Ltd., has awarded the contract for the construction of a smelting plant to M. P. Cotton, 1537 Matthews St.

Saskatchewan

REGINA—The City Council plans to install a filtration and softening plant for the city's water supply.

Ontario

CONISTON—The Mond Nickel Co. will make improvements to its plant and install additional machinery. C. V. Corliss, manager.

NORWAY—The city plans to build a sewage disposal plant. Estimated cost, $45,000. J. Brown, engineer.

WELLAND—The Maple Leaf Milling Co., Ltd., will rebuild its mill recently destroyed by fire. R. Cooper, manager.

Quebec

EAST ANGUS—The Brompton Pulp & Paper Co. plans to build an addition to its plant. Estimated cost, $60,000. D. L. Spence, 246 Beaver Hall, Montreal, architect.

VERDUN—The city is having plans prepared by A. E. Cohy Sons, engineers, City Hall, for improving and enlarging the waterworks and filtration plants. Estimated cost, $200,000.

Coming Meetings and Events

THE AMERICAN CHEMICAL SOCIETY will hold a meeting in Buffalo, April 7 to 11.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its annual meeting in New York City from April 3 to 5.

THE INTERNATIONAL MINING CONVENTION will be held in Vancouver, B. C., Canada, March 17-19.

THE NATIONAL FOREIGN TRADE COUNCIL will hold its sixth National Foreign Trade Council at the Congress Hotel, Chicago, Ill., on Thursday, Friday and Saturday, April 24, 25 and 26, 1919.

THE SOCIETY OF INDUSTRIAL ENGINEERS plans a national conference at New York March 18-21 at the Hotel McAlpin, at which there will be a discussion of labor by both employers and labor leaders. Internal plant organization and also the elimination of fatigue will be other leading topics.

Manufacturers' Catalogs

DE LAVAL STEAM TURBINE CO., Trenton, N. J., has issued a 32-page catalog describing standardized geared turbine units for marine service. The gain in fuel economy of the steam turbine over the reciprocating engine is stated to be approximately 25 per cent. The geared turbine weighs about half as much and occupies less than a third of the cubical space required by the engine. It is also more accessible and easier to repair, the expense for supplies and attendance is considerably less. The new publication describes the details of construction of turbines and gears and also various turbine-driven auxiliaries, including lighting sets, circulating pumps, boiler feeders, etc. A new development is the centrifugal pump for the continuous purification of the oil used in the turbine and gear bearings and on the gear teeth.

THE CRESCENT BELT FASTENER CO., 381 Fourth Ave., New York, wants all interested companies to take advantage of the bulletin and service chart entitled "Why People Buy Crescent Belt Fasteners," which may be obtained upon request.

THE WALTER A. ZELNICKER SUPPLY CO., St. Louis, Mo., has just issued Catalog No. 259, on new and used tanks.

THE LAKEWOOD ENGINEERING CO., Cleveland, Ohio, calls attention to Bull. No. 25, which shows the Lakewood line of storage battery tractors and trucks for all kinds of industrial haulage. On page 14 is an unusual table giving the type of trailers recommended for different classes of work, which is based on actual tests. Another interesting feature is the standardization of a few types of trailers instead of making a great number of different designs, which results in the higher development of each standard trailer.

WILSON WELDER & METALS CO., INC., New York, has just received from the press a catalog entitled "Repair of the German Ships," which was the biggest welding repair job in the history of the world. Many interesting illustrations are given showing cylinders before and after welding.

THE BROWN HOISTING MACHINERY CO., Cleveland, Ohio: Catalog K 1919 illustrates and describes in 96 pages Brownhoist locomotive cranes. This attractive catalog deals with buckets, capacities of cranes, clearances of cranes, coal and coke handling, construction work, 3-5 and 30-40 ton cranes, dock, dragline, electric, excavating, foreign and gasoline-driven cranes, lumber handling, magnet work, orange-peel, ore handling, pile drivers, portal-pier, sand handling, shipbuilding, special cranes, stone handling, wharf cranes and work-car cranes.

THE EASTMAN KODAK CO., Rochester, N. Y., has just issued a price list of Eastman organic chemicals.

THE CHAS. A. SCHIEREN CO., New York City, has recently received from the press a price list which differentiates the various brands of Schieren beltings not only by name and marking but also by grades and weights. This is a valuable feature to the buyer, as it enables him to select by name a Schieren belting which will meet his specifications, and he will know exactly what to expect when ordering by name. It also obviates, to a great extent, chances of the buyer selecting a belting largely upon a price basis, as the specifications show what can be expected of the various brands, in actual service. In other words, while the detail specifications enable the buyer to select a brand of belting best suited for his service, these same specifications also tend to keep him from selecting a brand which would not do his work satisfactorily. This company has also issued an attractive catalog entitled "The Story of Schieren Beltings," which is really a textbook on the leather belting business, and is handy for a reference book. The business of tanning hides and manufacturing the leather into belting is treated in a thorough manner, step by step, and many illustrations are given, in colors.

THE CUTLER-HAMMER MFG. CO., Milwaukee, Wis., is distributing the 1919 edition on wiring device written in Spanish, which has 24 pages. It lists and illustrates the majority of the C-H wiring devices shown in the 1919 English catalog. We have also received the catalog on C-H Wiring Devices,' Push Button Specialties (written in English), which gives in 64 pages a description and a list of push sockets, switches, a table listing conduit fittings made by eleven manufacturers, interchangeable plugs and receptacles, automobile lighting switches and control switches.

Warning! Beware the Gas-Mask!

A WORD of caution—perhaps it should be repeated many times and in many places—is in order regarding the indiscriminate use of the Army gas-mask. These can readily be had, either from returning soldiers or from dealers—as apparently there is little to prevent a manufacturer from producing a replica for sale. Men from the other side have implicit confidence in them—this was drilled into them in the back areas and later became strengthened from their own observation in the fighting line; without a mask, a man was a casualty; with a mask, all manner of "hell pepper" couldn't touch him.

Naturally these men will now not hesitate to don a mask and rush into almost any smoke or fume filled room, sure of that adequate protection which is utterly lacking in many instances. The confidence so carefully built up in the Army must be dispelled in civil life, and anyone who cherishes a gas-mask against a time of emergency should be carefully warned as to its limitations.

It is not widely realized that the nervous system cannot detect a deficiency of oxygen. The remarkable sensibility to "close" or "stuffy" atmosphere is a reaction against excess carbon dioxide rather than against lack of oxygen. Thus a normal person gradually deprived of oxygen, either in a test chamber or by ascending to extremely high altitudes, does not realize that he is being gradually stifled by lack of that necessary element and he suddenly loses consciousness without any preliminary warnings.

Herein lies the danger of indiscriminate use of the Army gas-mask. It is a gas-filter, pure and simple, designed to remove from the air the generally minute percentages of excessively poisonous gases which characterize the modern battle area. But carefully note that nowhere, except in the immediate proximity of a shell-burst, is the amount of toxic gas sufficient in amount materially to reduce the actual amount of oxygen passing through the breathing apparatus and entering a man's lungs.

A little consideration immediately indicates how different are conditions in a burning structure, a smoke flue, or a gas-filled room. Here a large proportion of the oxygen has already been consumed and replaced by such gases as carbon monoxide, carbon dioxide, sulphur dioxide, methane or ammonia. Even though the canister-filling would remove such gases (which in general it will not), the amount of oxygen contained in a lungful of the resulting atmosphere is quite insufficient to maintain life, and the result is the speedy collapse of the unwary victim. To live in such places a man must evidently wear a mask or helmet of a radically different type, that is to say, one which generates oxygen within itself.

The foregoing should not be interpreted as meaning that the tremendous amount of labor and thought expended on our Army gas-masks will be lost to industry. Quite the contrary. There is no reason why proper absorbents cannot be used effectively to clear the many dangerous fumes and smokes occurring in work-a-day life—different absorbents evidently will be used for the wide variety of gases encountered. But take especial pains to emphasize to miners, firemen, chemical workers and smelter men that the good old gas-mask which took them safely through the Argonne is powerless to aid them against fire-damp, in burning buildings, gas chambers or furnace flues. It's not the fault of the mask—it can be loaded so as to filter out almost anything, but it cannot supply a lack of oxygen which a man does not miss until it is too late!

Nitro-Aromatics vs. Nitroglycerine

WHEN the armistice was declared the War Department had 50 million pounds of TNT in its possession. The Government had built and equipped numerous plants for the recovery and nitration of toluol and the manufacture of picric acid, and in general there had been a great expansion in the production of nitro-aromatics. For want of more intelligent disposal somebody proposed to dump the TNT into the sea; and with the end of the war vast and expensive plants were promptly closed. What is the prospect for reasonable salvage?

Here is a situation, the future of which should appeal to industrial chemists of vision—the application of nitro-aromatics in the explosives industry, adapting a war munition to purposes of peace. The economics of the matter, as a correspondent points out elsewhere in this issue, favor the development of nitro-aromatics as against continued reliance on nitroglycerine. The proposal will encounter prejudice and inertia, but we doubt if even the prejudiced would contend vigorously that "it can't be done." If private initiative is lacking, the subject would be suitable for investigation by a Government agency.

Research Forbidden to Railway Companies

WE shall not undertake to discuss the merits of the Government administration of railroads from the standpoint of transportation or investment. Every free-born American citizen is supposed to hold that he knows how to run a newspaper or a railroad; and whether he can or not, he is entitled to his own opinion as to the management and the service rendered. The former director-general of railway administration, the HON. WILLIAM G. MCADOO, invited everybody to write him freely, and say what he thought about his work and the manner in which he did it; and if this invitation has been generally heeded we should say that enough had already been written concerning the business management of the properties.

There is one feature, however, which in our estimation has not been adequately discussed, and that is the complete cessation of industrial research and of the development of natural resources of the territories served by the various railways. There has been a great deal of boasting over the "cutting down of unnecessary expenses," and if geological surveys and industrial departments are held to be "unnecessary expenses" we think it time to put a crimp upon the boasting.

There are many old and tried aphorisms which are sound in doctrine if intelligently applied; but when the same old saws are offered as excuses for doing the wrong thing they become about as vicious as German propaganda. The study of the resources along the line of a railroad is its first step in the recording of assets that may be made available. Sometimes it is a good while before such assets may be realized, but that is no reason why they should be neglected. We are reminded of certain successors to the late SIR WILLIAM PERKIN in the manufacture of dyes in England. They were intensely practical men. They had no time for such nonsense as intangible things. SIR WILLIAM'S extensive scientific library was not wanted. His arrangements with leading chemists in academic life were canceled. The chemists engaged in research were discharged. As long as they could keep good foremen in the works and were sure they had the right "formulas" they were satisfied. Then, before they knew it, they were being undersold with German goods in their home town, and in a few years more they were practically driven out of business.

This was not a distinctly British view that muddled the minds of those Englishmen to their undoing and the loss to their nation of a great industry. It was the same distorted view that is still all too popular in this country: the notion that anything that cannot be tagged with the dollar mark of so much cost and such and such a selling price is to be discarded because it involves unnecessary expense.

We do not profess to have valuable opinions about ton-mile costs, but we do claim to know something about raw materials. The railroads of the South, where an almost illimitable store of mineral treasure is to be found, were doing splendid work before the war by having the territories adjacent to their lines surveyed as to their natural resources. If this had not been done we should have been in more than one sore dilemma during the past four years. We regard it as no less than a national misfortune that work along this line should not only have been discontinued, but effectively prohibited, so far as the railways are concerned.

We thought the war had taught us the value of applied science in industry. It sometimes seems as if some of us had learned to repeat the slogan without understanding what it means.

An Appraisal of the American Potash Industry

AMERICAN potash producers are passing through worrisome times. Six months ago the cry arose from every hand, "Get us more potash." With the cessation of hostilities and cheap Alsatian salts in prospect, the fertilizer market is paralyzed. Barred from this most important outlet, some four months' output has heaped up, threatening to overwhelm the modest financial resources of many producers. Unquestionably this tonnage has largely been produced in good faith in response to the national need, and as such constitutes an informal obligation upon the Government that it be utilized without loss to the manufacturers or the consumers.

But what of the future? A continuance of the past inflated prices of fertilizer potash will pinch the consumer, raise the cost of many necessary farm products, and tend to maintain the high cost of commodities which is primarily responsible for the present commercial stagnation. Economically it is bad. Technically

it is indefensible; why should processes be perfected for more complete or cheaper extraction, or for the utilization of by-products, as long the sale of one portion will cover the cost of slipshod, wasteful and defective operation?

And so we wish to protest most emphatically against limitation of imports, a tariff "wall," paternalistic subsidy, or any like schemes of this sort to be vigorously pushed by interested persons, all of them making for high-priced potash. Lest we be damned as free traders out of pot, we hasten to give cordial support to the Tariff Commission and its underlying principle, popularized as the difference in cost, here and abroad. What we wish to emphasize right here, however, is that 75 per cent and more of our 1918 production was made by processes which can meet fair foreign competition, eliminating the bogey of "trade-war."

In 1918 natural brines produced 40,000 tons K_2O from plants aggregating double that capacity. Nebraska lakes alone yielded about 55 per cent of last year's output, at a cost estimated by us Nov. 15, 1917, at $40 per ton K_2O plus interest, amortization, profit and royalty. Figures of $110 per ton quoted by others must include large amortization allowances. Considering that the 1912-1914 price of German muriate f.o.b. American port was $65 per ton K_2O (even though it had been sold under trade-war conditions at a much lower price), it appears that the most important branch of our industry will need but a moderate tariff if coast-to-interior rail freights are established and the financial agreements are sound.

Our most promising immediate source of local supply lies in cement-kiln dust. It yielded but 1500 K_2O last year from installations rated at 3500 tons, yet if all cement plants would recover this product some 70,000 tons of K_2O would result. It is possible to build a plant to handle the gases and fine dust from a 1000-bbl. plant for $30,000, which by simple methods will collect 95 per cent of the volatilized potash. Such an installation has made potash at $50 per ton K_2O, which cost includes labor, power, repairs and renewals, interest and amortization, but does not include a proper and material credit for recovered slurry. Evidently here is an operation which can stand on its own feet. The failure of cement-makers to embark on potash recovery has been ascribed to the hesitation to make plant investments without more attractive returns, but the day will come when a cement kiln without its potash scrubbers will be as rare as a smelter without a dust chamber. Potash from iron blast-furnace dust also is a promising source, though possibly further in the future.

No industry should be permitted to maintain a high price for the benefit of an inconsiderable few of its own number and to the disadvantage of the consuming public, in the face of a low-priced international supply and an actual and prospective source of cheap substance at home.

Commodity Values and Construction Work

THE United States Government is engaged in an effort to bring about a resumption of construction activities in the country. This is a very progressive country and matters are so aligned that we are not busy unless we are engaged in a great deal of new construction. Our natural resources are so great and our labor is so efficient that nothing like all the labor is given employment if we are engaged simply in maintaining our facilities and producing the things that we currently consume. Also, we make so much money, such large profits, that we have in the normal year a great deal of new capital that must be invested or lie idle. New construction, therefore, is necessary if there is to be normal activity.

In the latter part of March the Industrial Board of the Department of Commerce, which is engaged in an effort to deflate war prices in the interest of stimulating construction work, reached an agreement with the iron and steel producers whereby certain reductions in prices were effected. The character and extent of the reductions, as well as of those which occurred last December, are referred to in the market report on iron and steel in this issue. Comparisons are frequently made with prices before the war, the favorite period being the ten years 1904 to 1913 inclusive. The investor may observe that prices at this writing compare with ten-year pre-war averages as shown below. Prices of the non-ferrous metals refer to the common brands, cents per pound at New York, while the steel price is a weighted average of the leading finished steel products, in cents per pound, Pittsburgh. The pre-war price is the ten-year average of quotations, 1904 to 1913.

	Pre-war	Present	Change Per Cent
Copper	15.36½	15.25	— 1
Spelter	5.84	6.52½	+12
Lead	4.64	5.20	+12
Aluminium	28.50	29.00	+ 2
Antimony	9.88	6.62½	−33
Steel	1.80	3.25	+81

Of the five non-ferrous metals cited three are higher than before the war, while two are lower. If one struck an average of the five there would be a net decline, but that would be misleading, since antimony is relatively unimportant. No one can ignore copper, however, which has experienced a complete deflation under a billion-pound stock on hand, which is some 600 million pounds in excess of normal stock.

Steel, however, is still nearly double its pre-war average. That is something very difficult to explain. The steel producers point out that labor is very high, and when reminded that rail mills are almost automatic, while the modern blast furnace is composed largely of "labor-saving" devices, they rejoin that it requires labor to mine the coking coal and the ore, to transport materials and to make the machinery which the furnaces and mills use. The argument is frequently received as conclusive, but when steel and the non-ferrous metals are set side by side it becomes very difficult to explain why the arguments that have been accepted to explain steel's 81 per cent excess over the pre-war average do not have some considerable application to the non-ferrous metals.

What is the investor going to do about it? The steel that sold at pre-war prices is sold. It is not available. The pre-war price is interesting only as it may possibly furnish a guide as to the course of the market in future, but if steel had to come down, why has it not done so? Being a construction material in particular, why has not the absence of any considerable amount of new construction in the past few months brought it down with a crash? The investor wants to know whether it will come down in future, whether he will save money by waiting. He also wants to know, and this is a point frequently overlooked, whether he would make money by investing, even if he could not save by waiting.

Readers' Views and Comments

Potash Recovery

To the Editor of Chemical & Metallurgical Engineering

SIR:—I desire to call your attention to two articles published in your issue of Sept. 26, 1918, during the Chemical Show, one by Dr. J. S. Grasty and one by Mr. Lynn Bradley.

Dr. Grasty, in his article, gives a table, on page 437, which he precedes by the following statement:

Table V, showing the cost of producing pig iron, depending on the kind of ore used, and the estimated results in potash recovery and profits therefrom by the erection of a Cottrell electric precipitator at a 200-ton iron blast furnace, was prepared in collaboration with Mr. Lynn Bradley, chief engineer of the Research Corporation.

In Mr. Bradley's article, in the same issue, a table on page 459 is preceded by the following statement:

The following table has been compiled to show the economic importance of these ores as a source of potash, the figures having been based on experience at several other furnaces as well as on the data obtained in connection with these particular ores and at various iron furnaces in the South. The table has been submitted to experienced blast-furnace operators for suggestions and criticisms.

I am attaching a table which, excepting for the last item, is an accurate reproduction of both of these tables, so that the figures obtained by each author may be compared. Dr. Grasty's figures are headed by the letter "G". Mr. Bradley's figures are headed by the letter "B".

It is quite evident that they both have started with the same coke and the same limestone, as their figures are identical for these two materials; that they both based their figures on the same Cambrian ore and on the same brown ore, as the analyses of the materials given by both of them are identical for both ores excepting that Dr. Grasty reports 6 per cent H_2O in the brown ore column, while Mr. Bradley reports 6 per cent of lime magnesia. The potash contained in the three ores is the same for both authors.

Based on exactly the same figures for No. 1 Cambrian ore and No. 3 brown ore, Mr. Bradley and Dr. Grasty arrive at different conclusions. While they both find the same total potash content per ton of iron for No. 1 ore, they arrive at different losses of potash in the slag and elsewhere for the same ore. Dr. Grasty deducts 20.96 lb. for the losses, while Mr. Bradley deducts 10.4 lb. Dr. Grasty, therefore, finds 78.54 lb. potash collectible, Mr. Bradley, 89.1 lb. from the same ore. In the No. 3 ore, the same sort of discrepancy exists. Dr. Grasty allows 23.46 lb. of potash for losses per ton of iron, while Mr. Bradley allows 14 lb. per ton of iron, so that Dr. Grasty, of course, figures 10.51 lb. of potash is collectible, while Mr. Bradley figures that 19.97 lb. of potash is collectible per ton of iron.

Dr. Grasty makes an estimate of return which shows that unless a furnace runs on No. 1 Cambrian ore, it can expect no net return from the potash collection. He estimates the annual operating cost of a precipitator at a 200-ton furnace at $165,000. Revenue from potash on a furnace running on No. 2 red ore and No. 3 brown ore is so small, according to Dr. Grasty's figures, that it could not possibly, even with a 40 per cent water-

	No. 1 Cambrian Ore		No. 2 Red Ore		No. 3 Brown Ore

soluble collection, show any profits from the potash value at the extreme price of $5 per unit.

Reducing this to a 100-ton basis, and comparing Dr. Grasty's figures for return at $5 per unit of K_2O with Mr. Bradley's figures reduced to the same basis, there is a very great discrepancy to be found. Dr. Grasty finds the revenue to be $316,123 per 100 tons of iron per annum, while Mr. Bradley finds a revenue of $623,-700. The latter figures are slightly less than twice the former figures. Starting with No. 2 ore, with very little difference in composition and having exactly the same potash content, Dr. Grasty finds a gross revenue of $9,922 per hundred tons of iron per annum for the potash, while Mr. Bradley finds, for the same conditions, $97,800 revenue. The latter figures are nearly ten times the former. For No. 3 brown ore, Dr. Grasty shows a revenue of $40,463, while Mr. Bradley shows a revenue of $140,600. The latter figures are nearly four times the former.

Since Dr. Grasty comments that his table was worked out in co-operation with Mr. Bradley, it is worth while finding out how these two authors, in two papers, came to such extremely different results. Mr. Bradley's figures for potash content for ores No. 2 and No. 3 compared with the losses that he allows for these two ores check with results obtained by us in actual electrical precipitation tests on a semi-commercial scale. The ratio between his loss and the total potash content is similar to the ratio we have found. I cannot understand Dr. Grasty's deduction in ore No. 2 of 31.28 lb. out of a total of 34.43 lb. Given the same operating conditions on all three ores, even if the slag volume varies, I cannot conceive of any reason why there should be such a tremendous difference. I believe that for the No. 2 and No. 3 ores, Mr. Bradley's figures of losses approximate the actual conditions. For No. 1 ore, I hardly believe that either the figures of Dr. Grasty or Mr. Bradley are correct. It is evident that there has been an assumption that the same percentage of slag would be potash for all three ores, the lean and the rich.

Tests made by us on ferromanganese furnaces indicated that when the ores are richer in potash, the greater is the amount of potash lost in the slag. I am, therefore, of the opinion that no such condition as indicated by Messrs. Grasty and Bradley exists in actual practice. Our tests, while not conclusive, have led us to believe that with a rich ore, such as shown in No. 1 Cambrian, there is a loss of about 50 per cent in normal blast-furnace operation of the potash, while the other 50 per cent is recoverable. I believe, however, that this loss can be cut down to 30 per cent by proper methods of treatment.

In connection with the costs, information obtained by us in running semi-commercial tests indicates that the cost of operating precipitators for a 200-ton blast furnace is nearer $70,000 per year than $165,000. Per hundred tons of iron per annum the chargeable expense to the potash collection would be about $35,000. This would make the cleaning of gases on furnaces running on ores as poor as Nos. 2 and 3 a very profitable undertaking. For No. 2 ore, based on Mr. Bradley's figures of gross revenue, the net returns would be about $62,-000 per hundred tons of iron per annum, while on No. 3 ore the returns would be a little more than $105,000 for the potash per hundred tons of iron per annum.

The days of $5 per unit potash are about over. There will be a natural tendency to determine what might be the profits on a $1 per unit basis. Our figures for operation are about $42,000 a year for a 200-ton furnace when potash sells at $1 per unit. This difference is due to the smaller royalty paid on the cheaper potash. At that rate, the operating expense per hundred tons of iron per annum is $21,000. The practice is to run on ores running much higher in iron than No. 2 red ore, and the general practice is closer to the ores shown under column No. 3 brown ore. With potash selling at $1 per unit, according to Mr. Bradley's figures for No. 3 brown ore, which I believe are correct, there will be a revenue of $28,120 per hundred tons of iron per annum for the potash content in the dust recovered by electrical precipitation. This will yield a net revenue of over $7,000 per hundred tons of iron per annum for the potash recovered. There are a number of furnaces, however, running on a much richer ore.

While we have not completed our examination and we cannot therefore make the following as a definite statement, our initial analyses show that a brown ore in the South is running about or close to 1¼ per cent of potash. This ore also runs over 47 per cent of iron.

It would seem from Dr. Grasty's figures that there are no potash values to yield a net revenue even at $5 per unit from either the No. 2 or the No. 3 ore, while the revenue from the No. 1 ore is considerable. If the corrections as designated above were made, the No. 1 ore would yield a revenue about one-third less than shown in Dr. Grasty's figures.

I cannot understand, however, how these two authors drifted so far apart in their final conclusions when using practically the same original data and working in collaboration with each other.

An Example of Crystal Crushing

To the Editor of Chemical & Metallurgical Engineering

Sir:—In your issue of Jan. 15 on page 72 appears a short article on "An Example of Crystal Crushing," in which the author states his opinion that the gray or silky spot usually seen in the center of the otherwise crystalline fracture of a medium-carbon steel test-bar is due to the fact that "the crystals in the interior of the bar were crushed during the elongating of the bar before rupture." The gray spots mentioned have often been seen in tensile tests of good-quality rails in this laboratory and have been the subjects of microscopic examinations. These examinations have always shown that there was no greater crushing or distortion of the crystals in the metal that had the gray fracture than there was in the metal with the crystalline fracture. Since the gray spots were always seen only in steel that contained an appreciable amount of ferrite, while steel without ferrite had a purely crystalline fracture, and steel composed chiefly of ferrite had a fracture that was all gray or silky, the opinion was formed here that the gray part represented a slow separation through ferrite, while the crystalline part of the fracture repre-

sented the final instantaneous break through the cleavage planes of the pearlite.

This, of course, does not explain why the silky or supposedly ferrite fracture should occur only at the center of the bar, when the microstructure was found uniform throughout, as it usually was. A consideration of the effects of the reduction of area, however, which accompanies all elongation of test-bars, may explain this. When the test-bar is elongated the outer particles of metal move not only lengthwise, but also inward toward the central axis, and as the circumference of the bar contracts the outer particles must move past each other to permit this contraction. Thus near the surface of the bar the increase in length is partly taken up by a sidewise rearrangement of the particles, while at the center the contraction is practically nil and the elongation is effected more largely by straight lengthwise movement of the particles. For this reason the tensile strains at the center are such as might be expected to cause fracture of the ferrite, being the weaker constituent of the metal, while nearer the surface the inward flow of metal would prevent the ferrite from breaking. Finally the inner fracture would become so large that the outer metal, even though hardened by slipping, could no longer sustain the load, and it would then break suddenly through its cleavage planes, giving a crystalline fracture. In other words, the formation of the silky center with crystalline rim is considered analogous to that of the common cup fracture of soft steel, with its gray silky center and sloping sheared rim. This explanation is believed to be more reasonable than one based on an assumed central crushing, which is not actually observed to be any greater than the normal distortion of the metal near the surface of the fractured test-bar.

Future of the Potash Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—What of the future of the American potash industry? Certainly it has been shown that American resources are adequate to supply American demands. But will these be further developed, or will the potash monopoly be handed back to Germany? If the public —the Government—now that the international crisis is over, loses its interest in the domestic industry and surrenders the trade to the unrestricted hands of those who operate without regard to the public weal or American commercial independence, without sentiment, potash will be purchased where it can be obtained the cheapest. And German potash, if admitted without restrictions, will be the cheapest potash. German subsidies will see to that.

It is said that Germany, to meet her financial obligations, will be forced to place an export tax on such commodities as potash, which will operate to maintain a high price for German potash. It must be remembered, however, that before an export tax on potash can be paid, potash must be exported; and before it can be exported, it will have to be re-established in foreign markets. For its re-establishment a low price must be its first requisite. There seems to be no reason to believe that the policy of the potash industry of Germany and the Government, with which German industry is closely allied, which prompted them to spend millions in potash propaganda abroad, will be reversed. It would appear that its exportation would now be of even greater importance than ever before.

The late military war was won by science, organization and efficiency. It was demonstrated that without these the man power combined with the wealth of the world was not sufficient. The victory that is now America's is America's only because she applied her science as an organized and efficient nation. With even greater emphasis can it be said of the trade war that is to follow the late military war that victory will be America's only in so far as we, her citizens, apply our science as an efficient organization, not as a heterogeneous mass of competing individuals. We have already made tremendous strides toward efficiency in insisting that a man purchase and use as little as he possibly can, not all that his credit will allow, and in the placing of curbs on the operations of the profiteer, the pooling of interests and the elimination of competition (which is the root and branch of inefficiency). These gains, which the President speaks of as "the by-products of war," must be retained and tremendously enlarged if we are to emerge from the second war with victory.

This efficiency, which will involve organization, coordination, co-operation, will consider waste on the one hand, both of labor and materials, and unused resources on the other. This will involve American potash in two ways. First, potash as a by-product (or with the aid of by-products) will become a permanent reality. Second, more conservativeness will be exercised in its use. We have been watching with interest the results on American agriculture of a great curtailment in the use of potash fertilizers. We have been asking ourselves how much the former wide and indiscriminate use of potash is based on actual scientific experimentation on American soils and how much on German propaganda.

American agriculture, formerly educated through German propaganda to the use of muriate and sulphate, with very little experimentation to determine the facts for itself, now finds itself applying to agricultural use a great variety of potash salts from a great variety of sources. There is a carbonate and sulphate from the alkali lakes of Nebraska, muriate from Searles Lake and kelp, carbonate from wood ashes and tobacco stems, and sulphate from alunite, cement mills, beet sugar residue and molasses. These are mixed in varying proportions with lots of other things present as impurities, and of questionable, if any, value as fertilizer. It has been a matter of ignoring ancient projudices in many cases or of doing without potash.

For example, muriate has been regarded as impossible for tobacco, and there potash has been regarded as a necessity. Are the tobacco growers using muriate, or are they doing without potash altogether where sulphate is not available? Does the presence of the small amount of borax found in muriate from certain sources act as a soil disinfectant and kill the soil bacteria essential to plant growth, or does it act as a stimulant, as poisons in small quantities so frequently do, and stimulate the growth of soil bacteria and thereby plant growth? Has the prejudice against muriate in California foundation in fact, or is it advice tendered by the German Kali Syndicate to the American farmers because sulphate formerly was produced only in Germany, and its use in our soils insured the use of German potash in place of local potash? It is unmistakable that there is a prejudice in California, for instance, against the use of muriate, the idea having been conveyed that

muriate contributed to the formation of alkali. It has not been possible to trace this idea to any experimentation actually performed by Californian experimentalists on Californian soils. It *has* been possible, however, to trace it to German propaganda. Knowing what we do about the nature of alkali in the soil and German propaganda, the question must be answered: Is not the Californian agriculturist making a mistake when he imports potash from Germany while ignoring the immense sources of potash at his own door?

Too much that is fundamental is involved in German science for us to question it without other reason than our late fear and hate of German world ambitions; but this we can surely say, that German propaganda has been written from the point of view of German profit.

Application of Nitro-Aromatic Compounds in Explosives Industry

To the Editor of Chemical & Metallurgical Engineering

SIR:—Two years ago I pointed out in your columns, March 15, 1917 ("The Application of Nitro-Aromatic Compounds in Explosives Industry"), that when the price of raw materials used in military explosives such as toluol and carbolic acid would drop from the abnormal prices of war to pre-war prices, it would be a good chance to convert TNT and picric acid into commercial blasting explosives. At the present time toluol and carbolic acid may be obtained at 18c. per gal. and 6c. per lb. respectively, and converted into TNT and picric acid at a respective cost of 10 to 12c. per lb. These purely military explosives cannot be used directly in commercial work, so it may be necessary to dilute and bring them to the grade of other standard blasting powders, like 40 per cent and 60 per cent standard dynamites, and at the same time eliminate the objectionable gases by mixing with oxidizing materials.

Thus there is a good opportunity for the picric acid and TNT manufacturers to continue making these nitro-aromatic compounds, by trying with a mixing outfit to convert these into commercial blasting explosives. The chance of success in explosive lines is much brighter than in the dyestuff business, which is almost overdone at the present time and does not present as big a future, commercially speaking.

During this period of waiting and readjustment it will be a good move on the part of TNT and picric acid manufacturers to investigate the possibilities of this proposition and to start preliminary tests and investigations on the properties and the powers of these new explosives. I have no doubt that they will find explosive engineers of tried experience and knowledge who will gladly co-operate with them in the application of TNT and picric acid to the explosive industry.

High Stacks for Smoke Dissipation

To the Editor of Chemical & Metallurgical Engineering

SIR:—I notice in your editorial on "The Metallurgy of Copper in 1918" (Jan. 1, 1919) that you speak of high stacks and the resultant smoke dissipation as a recent development of Mr. O'Gara. The old 300-ft. stack on top of the hill at Anaconda, which carried the smoke 1000 ft. above the valley and 500 ft. higher than the tops of the original stacks, was built for this very purpose, as the reports made at that time will show. This stack and the long connecting flue were built on my recommendation and as a result of my investigations made for the Anaconda company in 1903. It was soon followed by the construction of the 500-ft. stack at Great Falls for the same purpose of smoke dissipation. It is needless to mention that the new stack recently completed by the Anaconda company, and much larger and higher than the old one, has been built on top the hill alongside the old one.

In passing I might say that the tremendous development of the reverberatory furnace to almost its present size and efficiency immediately followed the completion of the Anaconda stack and can be traced directly to its operation.

I do not wish to detract in the least from Mr. O'Gara's work, but it is only fair that credit be given to the pioneer work in this direction, which was done some time before the Cottrell process was invented.

A Great Opportunity for Intelligent Location of Industries

To the Editor of Chemical & Metallurgical Engineering

SIR:—With the sudden emergence of the United States from a secondary political position to that of a world power, we have had thrust upon us one of the greatest opportunities for internal development ever placed before our people. The natural resources of our country are the envy of the world. Agriculture, mining, manufacturing and transportation flourish side by side and ever on an increasing scale. Abroad, however, we are known as producers of raw materials, principal among which are cotton, wheat, steel, meat and petroleum. Our manufactured products go largely to a home market—not more than 8 per cent of those produced in 1915 were exported.

It has been a creditable performance to export a large tonnage of raw materials to the artisans of Europe. Their distribution through the markets of the world as finished products by laborers of other countries is to our national discredit. It was very natural that masters of ships subsidized by their home Governments should carry the manufactured articles made by their own people and that export trade in articles manufactured in the United States should languish. But we are promised better treatment!

American shipping calling at the principal ports of the West Indies, of Mexico, South Africa, South America and the Orient is ready to carry our commodities to all of the great markets of the world. Our broadened national policy is particularly interesting to the manufacturer. Raw materials may be worked into their ultimate products at home, giving employment to many people and adding greatly to our national wealth and influence. To meet the situation we need to enlarge our existing plants and to add scores of new industries wherever conditions are favorable for their maintenance.

The modern American city is the nucleus of successful manufacturing and the phenomenal growth of 90 per cent of the towns of the United States is due to a recognition of this fact. There are about 175 cities in the United States each with a population of more than 25,000. Every one of these towns is a good location

for *one* or *more* industries and the *best* economic *location for at least one.* This may be due to the presence of an important raw material, a remarkable climatic condition or an unusual market. The iron ore industry of Duluth is an example of the first; the growth of the moving picture business at Los Angeles is an example of the second; and the Alaskan trade controlled by Seattle illustrates the third.

No other branch of industry can excel manufacturing from a labor standpoint. Employment is usually constant throughout the year. Both male and female help is utilized and under our present financial system, payment is prompt, with a fair wage. Capitalists and bankers are eager to lend financial support to a legitimate manufacturing business, and expect a good return upon the investment, if it is well managed. Examples of remarkable dividend paying enterprises are the well established cotton mills of New England, the steel plants of Pittsburgh or the various plants of the General Electric Co. The average annual sales of a stable manufacturing business are usually about equal to the capital stock invested and the net income in many instances averages 20 to 25 per cent.

The accumulation of sufficient wealth conservatively invested to insure leisure tempts thousands of men to move into small cities, where they live useless and comfortable lives. If such men dictate the policy of a town it is placed on the traveling man's map as "dead." There are hundreds of such places pretty well distributed throughout our national territory. In the country roundabout, the wealth that the Creator placed in the ground remains unsought for, the land is aimlessly tilled, and the fruit rots on the trees.

We have just emerged from national scarcity of many things, and the lesson should awaken every live man of influence to a sense of responsibility and to line up the raw materials and the men and women of his locality to produce useful manufactured commodities for the people of the world. One good industry employing a thousand people will transform a self-sufficient "retired business men's" town into a thriving village or city. One live man can make this change, with proper backing from the controlling financial forces.

Until very recently bankers have preferred to handle real estate and mortgages than to lend to manufacturers. In many instances, foreclosures on mill property have been the direct result of a short-sighted system of discrimination against even the best commercial paper. A bank is a public institution, one of the purposes of which is service to the community. If manufacturing has not been popular among the business men of a town it is the duty of the local banks to employ technical assistance, and determine what can be made and sold to advantage in that locality. With proper financial support a plant may be erected and a business started.

While the banker has been conservative in industrial matters, our business men of many cities have combined forces and have, through their commercial associations, attracted industries that have enriched the life and business of the town in every way.

We foresee an intensive study undertaken by every municipality to determine what can best be manufactured in that place. We remember Schenectady as a sleepy cobblestone-paved town of 12,000 people. The presence of an industry of national scope and interests has made a modern city of nearly 100,000; 25,000 of these are men and women who earn good wages with one concern.

If a town has grown through the manufacture of a raw material the supply of which will soon be exhausted, the public spirited citizens of the place should attempt to find a substitute before the actual death of the business. The sawing or handling of lumber is an example. Many prosperous mining towns of the West are depopulated when paying ore ceases to be found.

Among the fundamental elements of a location to be studied are the following:

Raw Materials	Climate
Market	Hygienic Conditions
Transportation	Public Utilities
Labor	Housing
Water Supply	Banking Facilities
Power Cost	Taxes and Insurance

Education and Public Spirit
